Detection of tyrosine kinase activity using the PHERAstar in AlphaScreen™ mode

Franka Ganske and Marjan Orban
BMG LABTECH, Offenburg, Germany

Application Note 153 Rev. 02/2007

Materials and Methods

- AlphaScreen™ tyrosine kinase assay performed on BMG LABTECH’s PHERAstar including a laser
- Z’ value of 0.93 indicates a highly robust assay combined with high quality instrumentation
- Sensitivity determined to be ≤ 100 amol biot-LCK-P per well

Introduction

Tyrosine kinases are important regulators of cellular processes that include cell cycle progression, metabolism, and apoptosis. Kinases have been found to be involved in e.g. cancer and cardiovascular diseases; therefore, molecules that modulate kinase functions are expected to be promising new drugs. There are different homogeneous technologies which can be used to perform kinase assays. In this application note we will describe the performance of a tyrosine kinase assay using the AlphaScreen™ (amplified luminescent proximity homogeneous assay) method and an AlphaScreen™ specific excitation laser on BMG LABTECH’s PHERAstar.

Assay Principle

The AlphaScreen™ assay uses the diffusion of singlet state oxygen from Donor to Acceptor beads. Upon laser excitation at 680 nm of Donor beads ambient oxygen is converted into singlet oxygen released at a rate of up to 60,000 molecules per second. Singlet oxygen molecules have a short lifetime (4 µs in aqueous solutions) and diffuse no more than 200 nm. When a biomolecular interaction brings the Donor and Acceptor beads in proximity, the singlet oxygen reaches the Acceptor bead and a cascade of chemical reactions is initiated producing a greatly amplified luminescence signal in the range of 520 - 620 nm. The AlphaScreen™ P-Tyr-100 assay (figure 1) is based on a sandwich assay principle.

**Fig. 1:** Principle for an AlphaScreen™ tyrosine kinase assay

After tyrosine kinase phosphorylation, a biotinylated polypeptide substrate is sandwiched between a streptavidin(SA)-coated Donor bead and an anti-phosphotyrosine antibody conjugated Acceptor bead. Phosphorylation of the polypeptide by the tyrosine kinase results in an increase in the luminescence signal.

Results and Discussion

To demonstrate the functionality of the AlphaScreen™ assay and the performance on the PHERAstar, a titration curve with a biotinylated and phosphorylated polypeptide (biot-LCK-P) was performed with the anti-phosphotyrosine antibody (Figure 2).
The concentration of biot-LCK-P used was in the range of 5 pM to 17 nM and the final assay volume was 17 µL per well. The resulting titration curve (Figure 2) very closely corresponds to the curve published in the kit protocol. In order to show that there is no significant well to well variation, the same assay was performed with 20 replicates at both a single biot-LCK-P concentration (5 nM) and a control concentration (without biot-LCK-P).

![Graph of AlphaScreen™ values for 20 replicates at a constant concentration (5 nM) of biotinylated and phosphorylated LCK and a control containing no protein]

Figure 3 shows the high consistency of well to well measurements when using the PHERAstar. The resulting 2.2 %CV (for 5 nM biot-LKC-P) also demonstrates consistent measurements. From these assay data, a representative Z’ value of 0.93 and an LOD (limit of detection) of ≤100 amol biot-LCK-P per well were calculated.

**Conclusion**

AlphaScreen™ tyrosine kinase assays performed on the PHERAstar result in very consistent values for replicate wells. As a characteristic parameter for the quality of the assay, a Z’ value of 0.93 was calculated, which represents an excellent assay performance. Z’ values between 0.5 and 1 indicate a highly robust screening assay and reflect high quality of the instrumentation.

In drug discovery, successful detection strategies have to be compatible with miniaturized HTS. The multimode HTS reader PHERAstar shows great performance in AlphaScreen™ mode as demonstrated with the tyrosine kinase assay in 384-well small volume plate format. The easy to use software allows simple assay optimization regarding sensitivity and read times. The PHERAstar has been designed to read all HTS detection modes (fluorescence intensity, time-resolved fluorescence, fluorescence polarization, luminescence, AlphaScreen™, and absorbance) in all plate formats up to 1536 wells.
