Figure S3 Wagering versus performance in the Iowa gambling task. The average fraction of participants making advantageous wagers every ten trials versus positive pack (correct) selections in the three different questioning conditions. The solid curves are the polynomials fitted to data for no questioning (No), opened-ended questioning (Open) and quantitative questioning (Quant.). The dashed line of slope 1 represents the expected fraction of participants wagering advantageously expected given full awareness. The data for quantitative questioning lies near to the line of slope 1 whereas the other two data sets do not.
