Supplementary Figure 1  Post-task cue ratings. Younger adults self-report increasing negative valence and arousal with loss cues and positive valence and arousal with gain cues in the anticipatory period. Older adults report increasing positive valence and arousal with gain cues, but only show increases in arousal and no change in valence as the magnitude of loss cues increases. Points are plotted according to group means (x,y = valence, arousal). X-error bars correspond to standard error of valence means, and Y-error bars to standard error of arousal means.
