The mystery of the microscope in mud

A rare brass microscope was discovered in mud dredged from canals in Delft, the Netherlands, in December 2014. The instrument (pictured, left) is thought to have been made by Dutch pioneer microscopist Antony van Leeuwenhoek (1632–1723; see P. Ball *Nature* **520**, 156; 2015) and is an important find — if it is genuine. The last Leeuwenhoek microscope in public hands was a silver instrument that sold for more than US\$500,000 in 2009.

The ten microscopes attributed to Leeuwenhoek are diminutive, comprising a biconvex lens sandwiched between two riveted body plates. A positioning screw holds a stage block and a pin to secure the specimen. A smaller screw moves the stage block to focus the image.

The Delft microscope's design and dimensions are comparable to those of a Leeuwenhoek microscope in the Boerhaave Museum in Leiden. Although the lens is abraded, it would have given about 160× magnification.

The Delft find cannot be a replica. First, it has a rounded body plate — a comparable microscope in the Boerhaave Museum is rectangular (pictured, right), and a copy would have an identical configuration. Second, my analysis of the screw thread at the Cavendish Laboratory at the University of Cambridge, UK, shows that it is unlike threads produced by modern mechanical methods. The distance between the threads (or pitch) of the main screw is 0.9 millimetres, comparable with that in authentic instruments.

I am preparing a protocol through which the production details of all existing Leeuwenhoek microscopes can be scrutinized. Scanning electron microscopy should then be able to detect any forgeries.

Deforestation soars in the Amazon

Deforestation of the Brazilian Amazon is on the rise and not declining as you imply (*Nature* **520**, 20–23; 2015). Forest clearance has exploded since August 2014, according to satellite data from Brazil's National Institute for Space Research and the sustainable-development organization Imazon. Monthly clearance rates are several times those for the same months in the preceding two years.

The data on deforestation drivers in the studies you discuss predate the recent deforestation surge (D. Nepstad *et al. Science* **344**, 1118–1123; 2014 and H. K. Gibbs *et al. Science* **347**, 377–378; 2015). Brazil's currency, the real, is in free-fall, with no end in sight. Exchange rates against the US dollar mean that exports from Brazil are now considerably more profitable than last year, when the deforestation decline was occurring.

Prospects for the near term are not good. A key 2008 resolution from the Central Bank of Brazil, which links financing from public banks to environmental compliance, now offers only fragile protection in the face of a congress dominated by those in favour of agribusiness. Creation of new protected areas has been essentially paralysed, existing reserves continue to have their official status

removed, and government expenditure on enforcing environmental laws has been cut by 72%. Furthermore, political appointments are sending an anti-environmental signal to deforesters (see *Nature* **517**, 251–252; 2015), and plans for Amazonian roads continue as fast as money allows. The “battle for the Amazon” is far from won. **Philip M. Fearnside** *National Institute for Research in Amazonia (INPA), Manaus, Brazil.* pmfearn@inpa.gov.br

UK bioscientists push for crop policy

In assessing the next generation of plant-breeding techniques such as gene editing (*Nature* **520**, 131–132; 2015), the European Union (EU) should take into account criticisms of its current regulatory system for new crop varieties.

Last year's statement by the UK Biotechnology and Biological Sciences Research Council on genetic techniques for crop improvement suggests that EU regulations need to move beyond production methods and focus more on the benefits of newly introduced genetic traits (see go.nature.com/gsoiza).

The UK National Institutes of Bioscience, which contributed to the statement, seek prompt realization of the societal and

environmental benefits of these latest technologies. They are leading efforts to ensure that the best policy decisions are being made for plant (and animal) breeding in Europe and worldwide.

Marine protection is a UK priority

Scotland's government has responsibility for nature conservation in 61% of UK waters. As programme manager for the Marine Conservation Society in Scotland, I agree that the United Kingdom and its devolved governments should be making marine conservation a priority (see also *Nature* **520**, 585–586; 2015).

This summer, Scotland could become a global conservation leader following proposals for Marine Protected Areas (MPAs) for highly mobile species, including minke whales and basking sharks. These areas will soon be subject to public consultation. The hope is that they will then augment the 30 Scottish MPAs designated in summer 2014. Even at some of these sites, damaging fishing activity may still be continuing (see go.nature.com/hzkdzd). Present and future governments in Scotland and Westminster must take steps to keep the ‘P’ in MPAs.
