**Background:** Several recent studies demonstrated that microRNAs are stably detectable in plasma/serum. We tested whether miR-18a, which is located in the miR-17-92 cluster and reported to be highly expressed in tissues of oesophageal squamous cell carcinoma (ESCC), served as a plasma biomarker in patients with ESCC.

**Methods:** This study was divided into three steps: (1) confirmation of higher miR-18a levels in primary ESCC tissues and cell lines than normal ESCC tissues and a human fibroblast cell line. (2) Evaluation of the plasma miR-18a assay using quantitative RT-PCR by comparing results from 106 consecutive patients with ESCC and 54 healthy volunteers. (3) Evaluation of the assay for monitoring tumour dynamics in patients with ESCC.

**Results:** (1) Expression of miR-18a was significantly higher in ESCC tissues ( $P=0.0020$ ) and ESCC cell lines ( $P=0.0121$ ) than normal tissues and fibroblasts. (2) Plasma concentrations of miR-18a were significantly higher in ESCC patients than healthy volunteers ( $P<0.0001$ ; ESCC patients vs healthy volunteers (mean  $\pm$  s.d.):  $11.77 \pm 13.45$  vs  $0.73 \pm 0.54$  amol  $\mu\text{l}^{-1}$ ). The value of the area under the receiver-operating characteristic (ROC) curve (AUC) was 0.9449. Furthermore, the ROC curves to detect early ESCC such as pTis-1 and pStage0-I showed AUCs of 0.9479 and 0.9642, respectively. (3) Plasma levels of miR-18a were significantly lower in postoperative samples than preoperative samples ( $P=0.0076$ ).

**Conclusion:** Plasma miR-18a may be a very useful biomarker for cancer detection and the monitoring of tumour dynamics in patients with ESCC.

Oesophageal squamous cell carcinoma (ESCC) is the eighth most common cancer in the world and is the sixth leading cause of cancer-related death (Enzinger and Mayer, 2003). In Asian countries, ESCC accounts for ~90% of oesophageal carcinomas (Hiyama *et al*, 2007) and remains one of the most aggressive carcinomas in the gastrointestinal tract. Recent improvements in surgical techniques and perioperative management have reduced operation-related deaths during perioperative periods; however, ESCC still has extremely poor prognosis. Therefore, primary tumours must be detected at an early stage, and recurrent disease

must be diagnosed when it is still minimal or clinically occult, in order to improve the prognosis of patients with ESCC.

To identify biological factors involved in the malignant behaviour of ESCC, several recent studies have elucidated that certain molecules, such as p53, cyclin D1, and FAS, have important roles in tumorigenesis and the development of ESCC (Hollestein *et al*, 1990; Adélaide *et al*, 1995; Gratas *et al*, 1998). In clinical settings, however, few molecules have been assayed as therapeutic and/or prognostic biomarkers. Conventional serum tumour markers, such as carcinoembryonic antigen (CEA) and squamous

cell carcinoma antigen (SCC), have been used as convenient diagnostic assays (Kosugi *et al*, 2004; Mroczo *et al*, 2008) for early detection and monitoring the tumour dynamics of ESCC. These serum tumour markers, however, lack sufficient sensitivity and specificity to facilitate early detection of cancer. Therefore, the significance of detecting novel biomarkers using a less invasive diagnostic assay for ESCC should be emphasised.

In recent years, several studies have shown that microRNAs (miRNAs), which are involved in carcinogenesis and development of various cancers (He *et al*, 2005; Lu *et al*, 2005; Calin and Croce, 2006; He *et al*, 2007), are detectable in plasma/serum (Calin and Croce, 2006; Chen *et al*, 2008; Filipowicz *et al*, 2008; Ichikawa *et al*, 2012). Tumour-derived miRNAs are resistant to endogenous ribonuclease activity because these may bind to proteins, such as the Argonaute 2 protein and high-density lipoprotein (Arroyo *et al*, 2011; Vickers *et al*, 2011), or are packaged by secretory particles including apoptotic bodies and exosomes in plasma/serum (Hasselmann *et al*, 2001; Mitchell *et al*, 2008; Cocucci *et al*, 2009; Kosaka *et al*, 2010). Therefore, miRNAs can be present in a remarkably stable form (Mitchell *et al*, 2008; Hongyan and Guo-Chang, 2011) and the expression level of serum miRNAs is reproducible and consistent among individuals (Chen *et al*, 2008; Mitchell *et al*, 2008). Furthermore, secretory vesicles including miRNAs can function as intercellular transmitters (Valadi *et al*, 2007; Skog *et al*, 2008; Rechavi *et al*, 2009). These findings should open up a new and interesting field in the screening and monitoring of ESCC patients. However, to date, there have been few reports on the role of circulating miRNAs in plasma/serum of patients with ESCC (Zhang *et al*, 2010; Komatsu *et al*, 2011).

In this study, we tested miR-18a, which was located in the miR-17-92 cluster and was previously reported to be highly expressed in the tissues of SCC (Chang *et al*, 2008; Avissar *et al*, 2009; Gao *et al*, 2011; Liu *et al*, 2011). This cluster has been reported to have a potential oncogenic function in various tumours. Therefore, we hypothesised that miR-18a could be detected in plasma and may be a useful plasma biomarker for patients with ESCC. Consequently, we demonstrated that miR-18a was very useful for measuring plasma miRNA in ESCC among previous reported plasma/serum miRNAs. Our results provide evidence that plasma levels of miR-18 contribute to cancer detection and can be used to monitor ESCC patients to a clinically satisfactory degree of sensitivity and specificity.

## PATIENTS AND METHODS

**Patients and samples.** This study was approved by the Institutional Review Board of Kyoto Prefectural University of Medicine and each subject provided signed informed consent. Between November 2008 and June 2011, 106 consecutive preoperative plasma samples were collected from consecutive patients with ESCC, who underwent radical oesophagectomy (R0 or R1) at Kyoto Prefectural University of Medicine. Patient characteristics with respect to age, sex, venous invasion, lymphatic invasion, T-stage, N-stage, stage of disease, and resection status are described in Table 1. Preoperative plasma samples were collected from 106 patients with ESCC. All patients were pathologically diagnosed as having ESCC using surgical specimens and biopsies. Ten ESCC specimens were collected from patients undergoing oesophagectomy, and eleven normal oesophageal tissue specimens of the abdominal oesophagus were collected from patients undergoing total gastrectomy for gastric cancer because the non-cancerous oesophageal tissues of ESCC patients may exhibit dysplasia or potentially be cancerous tissue. As a control, plasma was collected from 54 healthy volunteers. Volunteers were medical personnel and patients with benign disease such as cholelithiasis.

Abbreviations: ESCC = oesophageal squamous cell carcinoma; ROC = receiver-operating characteristic. P-values were considered significant at 0.05.  
<sup>a</sup>Cutoff value of plasma miR-18a concentrations in healthy volunteers (ROC curve with Youden Index): 1.99 amol  $\mu\text{l}^{-1}$ .  
<sup>b</sup>The Mann-Whitney U-test and Kruskal-Wallis H-test were performed to compare plasma miRNA concentrations.  
<sup>c</sup>TNM classification.

They underwent medical examinations and did not have any oesophageal disease or other cancerous disease. The stage of tumours was assessed according to the Union of International Control of Cancer (UICC) classification (Sobin *et al*, 2009).

Peripheral blood (7 ml) was obtained from each patient at the same time before the initial skin incision for oesophagectomy, and healthy volunteer controls. Immediately after collection, blood samples were subjected to isolation of cell-free nucleic acids using a 3-spin protocol (1500 r.p.m. for 30 min, 3000 r.p.m. for 5 min,

4500 r.p.m. for 5 min) to prevent contamination by cellular nucleic acids. Plasma samples were stored at  $-80^{\circ}\text{C}$  until further processing. Resected specimens were fixed in formalin and embedded in paraffin for pathological diagnosis. Macroscopic and microscopic classification of tumours were based on the UICC/TNM staging system (Sobin *et al*, 2009).

**RNA extraction.** Total RNA was extracted from 400  $\mu\text{l}$  of plasma using a mirVana PARIS Kit (Ambion, Austin, TX, USA), and finally eluted into 100  $\mu\text{l}$  of preheated ( $95^{\circ}\text{C}$ ) Elution Solution according to the manufacturer's protocol. Using formalin-fixed paraffin-embedded tissues, total RNA was extracted from four slices of 15  $\mu\text{m}$  thick (total 60  $\mu\text{m}$  in thickness) using a Recover All Total Nucleic Acid Isolation Kit (Ambion), and then eluted into 60  $\mu\text{l}$  of Elution Solution according to the manufacturer's protocol.

**Protocol for the detection of microRNA.** The amounts of miRNAs in plasma were quantified by qRT-PCR using human TaqMan MicroRNA Assay Kits (Applied Biosystems, Foster City, CA, USA). The reverse transcription reaction was carried out with a TaqMan MicroRNA Reverse Transcription Kit (Applied Biosystems) in 15  $\mu\text{l}$  containing 5  $\mu\text{l}$  of RNA extract, 0.15  $\mu\text{l}$  of 100 mM dNTPs, 1  $\mu\text{l}$  of MultiScribe Reverse Transcriptase ( $50\text{ U } \mu\text{l}^{-1}$ ), 1.5  $\mu\text{l}$  of  $10 \times$  Reverse Transcription Buffer, 0.19  $\mu\text{l}$  of RNase inhibitor ( $20\text{ U } \mu\text{l}^{-1}$ ), 1  $\mu\text{l}$  of gene-specific primer (has-miR-18a; Assay ID: 002422, RNU6B; Assay ID: 001093), and 4.16  $\mu\text{l}$  of Nuclease-free water. For the synthesis of cDNA, reaction mixtures were incubated at  $16^{\circ}\text{C}$  for 30 min, at  $42^{\circ}\text{C}$  for 30 min, and at  $85^{\circ}\text{C}$  for 5 min and then held at  $4^{\circ}\text{C}$ . Next, 1.33  $\mu\text{l}$  of cDNA solution was amplified using 10  $\mu\text{l}$  of TaqMan  $2 \times$  Universal PCR Master Mix with no AmpErase UNG (Applied Biosystems), 1  $\mu\text{l}$  of gene-specific primer/probe, and 7.67  $\mu\text{l}$  of nuclease-free water in a final volume of 20  $\mu\text{l}$ . Quantitative PCR was run on a 7300 Real-time PCR system (Applied Biosystems) and reaction mixtures were incubated at  $95^{\circ}\text{C}$  for 10 min, followed by 40 cycles of  $95^{\circ}\text{C}$  for 15 s, and  $60^{\circ}\text{C}$  for 1 min. The cycle threshold (Ct) values were calculated with SDS 1.4 software (Livak and Schmittgen, 2001).

The amounts of miRNAs in plasma were calculated on a standard curve constructed with the use of synthetic miRNAs, the mirVana miRNA Reference Panel (Ambion). Standard reference miRNAs were amplified for each reaction. However, the expression of miRNAs from tissue samples was normalised using the  $2^{-\Delta\Delta\text{Ct}}$  method relative to U6 small nuclear RNA (RNU6B).  $\Delta\text{Ct}$  was calculated by subtracting Ct values of RNU6B from Ct values of the miRNAs of interest.  $\Delta\Delta\text{Ct}$  was then calculated by subtracting  $\Delta\text{Ct}$  of normal ESCC tissue from  $\Delta\text{Ct}$  of ESCC tissues. The change in gene expression was calculated with the equation  $2^{-\Delta\Delta\text{Ct}}$  (Akobeng, 2007; Sobin, *et al*, 2009).

**ESCC cell lines and culture.** ESCC cell lines, such as TE2, TE9, TE13, and KYSE70 and fibroblast cell line WI-38, were purchased from RIKEN Cell Bank (Tsukuba, Japan). WI-38 cell was cultured in Dulbecco's minimum essential medium: F12 medium and the others in Roswell Park Memorial Institute (RPMI)-1640 medium (Sigma, St Louis, MO, USA). All media were purchased from Sigma and supplemented with  $100\text{ ml l}^{-1}$  FBS (Trace Scientific, Melbourne, Australia). All cell lines were cultured in  $50\text{ ml l}^{-1}$  carbon dioxide at  $37^{\circ}\text{C}$  in a humidified chamber.

**Statistical analysis.** The Mann-Whitney test was used to compare differences in plasma miRNA concentrations and miRNA ratios between the cancer group and healthy group, and the Wilcoxon test was used to compare the paired plasma samples before and 1 month after oesophagectomy. A *P*-value of 0.05 was considered significant. Receiver-operating characteristic (ROC) curves and area under the curve (AUC) were used to assess the feasibility of using plasma miRNA concentrations as a diagnostic tool for

detecting ESCC. The Younden Index was used to determine the cutoff value for plasma miRNA concentrations (Akobeng, 2007).

## RESULTS

### Study design to develop a novel biomarker of plasma miRNA.

This study was divided into three parts: (1) Confirmation of higher miR-18a levels in primary ESCC tissue and cell lines than normal ESCC tissues and human fibroblasts. (2) Evaluation of the miR-18a assay using quantitative RT-PCR by comparing results from 106 consecutive patients with ESCC and 54 healthy volunteers. (3) Evaluation for monitoring tumour dynamics by the plasma miR-18a assay in patients with ESCC (Figure 1A).

### MiR-18a expression in primary ESCC tissues and ESCC cell lines.

To confirm whether miR-18a is highly expressed in primary ESCC, expression of miR-18a in 10 ESCC tissues and 11 normal oesophageal tissues was determined by quantitative RT-PCR. Also, human ESCC cell lines TE-2, TE-9, TE-13, and KYSE70 and a human fibroblast cell line WI-38 were evaluated by quantitative RT-PCR. Results are shown in Figures 1B and C after normalisation to control U6 expression. Levels of miR-18a were significantly higher in ESCC tissues than normal ESCC tissues ( $P=0.0020$ ; Figure 1B). Also, in ESCC cell lines, levels of miR-18a were significantly higher than in the fibroblast cell line and normal oesophageal tissues ( $P=0.0121$ ; Figure 1C). Consequently, expression of miR-18a was significantly increased in most ESCC tissues and cell lines, but not in normal tissues and fibroblasts.

### Evaluation of plasma miR-18a expression using quantitative RT-PCR in ESCC patients.

Next, we hypothesised that higher miR-18a expression in primary tumours would influence plasma levels of miR-18a in ESCC patients. To evaluate the appropriateness of this assay, we first conducted amplification by RT-PCR of a 10-fold serial dilution of the mirVana miRNA Reference Panel. The linearity of quantitative RT-PCR was confirmed from concentrations of 1 fmol to 0.0001 fmol of each synthetic miRNA, such as miR-18a ( $R^2=0.9919$ ) between the logarithm of the amount of input miRNA and Ct values (Supplementary Figure 1S). Although some investigators have determined quantities of plasma miRNAs by comparing internal control miRNAs (Ng *et al*, 2009), it remains controversial as to which miRNAs are suitable as internal controls for plasma assays. Therefore, we confirmed a linear correlation between the logarithm of the amount of input synthetic miRNA and the cycle threshold value on real-time PCR, as well as the feasibility of extracting total RNA and amplifying specific miRNA in plasma samples. Based on these findings, we utilised the absolute concentration for measuring plasma miRNA in this study (Supplementary Figure 1S).

Using this assay, circulating miRNA such as miR-18a was detectable in all samples from 106 consecutive ESCC patients and 54 healthy volunteers. The differential expression of plasma miR-18a in ESCC patients was compared with that in normal healthy volunteers by a waterfall plot (Figure 2A). Concentrations of miR-18a were significantly higher in plasma from ESCC patients than in healthy volunteers ( $P<0.0001$ ; ESCC patients vs healthy volunteers (mean  $\pm$  s.d.):  $11.77 \pm 13.45$  vs  $0.73 \pm 0.54\text{ amol } \mu\text{l}^{-1}$ ; Figure 2A). Representation of the data using an ROC plot showed strong separation between the two groups, with an AUC of 0.9449 (Figure 2B). To detect cutoff points that could discriminate cancer patients from healthy volunteers, we utilised ROC curves with the Younden index (Akobeng, 2007). An optimal cutoff point was indicated at  $1.99\text{ amol } \mu\text{l}^{-1}$  with a sensitivity of 86.8% and a specificity of 100%. Furthermore, plasma miR-18a concentrations in patients with early ESCC such as pathological (p) Tis-1\* or pStage0-I\*\* were significantly higher than those of healthy volunteers ( $P<0.0001^*$ ,  $P<0.0001^{**}$ ; pTis-1\* vs pStage0-I\*\* vs

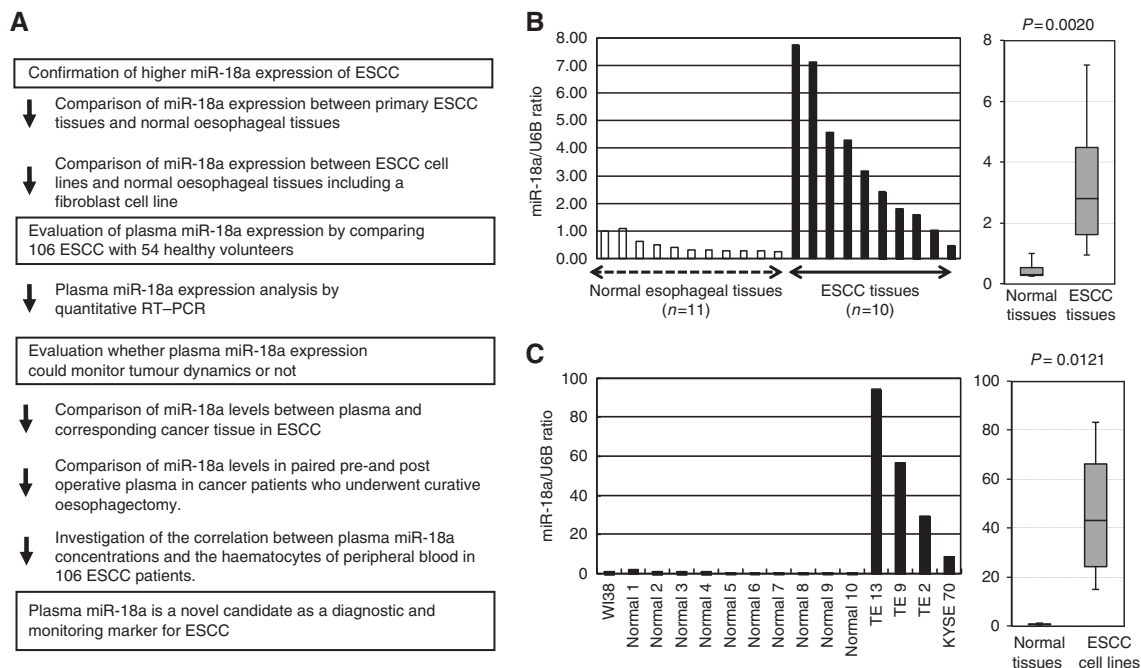

Figure 1. (A) Study design to develop a novel biomarker of plasma microRNA. (B) The expression of miR-18a in ESCC tissues. Differential expressions of miR-18a in ESCC tissues were compared with those of normal tissues by a waterfall plot. Expression levels of miR-18a were significantly higher in ESCC tissues than normal oesophageal tissues ( $P=0.0020$ ). The upper and lower limits of the boxes and lines inside the boxes indicate the 75th and 25th percentiles and the median, respectively. Upper and lower horizontal bars denote the 90th and 10th percentiles. (C) The expression of miR-18a in ESCC cell lines. Differential expressions of miR-18a in ESCC cell lines were compared with those of a fibroblast cell line and normal tissues. In ESCC cell lines, expression levels of miR-18a were significantly higher than in both a fibroblast cell line and normal oesophageal tissues ( $P=0.0121$ ). \*Normal means normal tissues including the normal fibroblast cell line, such as WI-38.

Figure 2. (A) Plasma miR-18a concentrations in 106 consecutive ESCC patients and 54 healthy volunteers. Using a real-time RT-PCR assay, circulating miRNA, such as miR-18a, was detectable in all samples from 106 consecutive ESCC patients and 54 healthy volunteers. Differential expressions of plasma miR-18a with ESCC patients were compared with those of normal healthy volunteers by a waterfall plot. Concentrations of miR-18a were significantly higher in plasma from ESCC patients than those in healthy volunteers ( $P < 0.0001$ ). The upper and lower limits of the boxes and lines inside the boxes indicate the 75th and 25th percentiles and the median, respectively. Upper and lower horizontal bars denote the 90th and 10th percentiles. (B) Receiver-operating characteristic (ROC) curve analysis in the miR-18a assay for detecting ESCC patients. Receiver-operating characteristic analysis showed the greatest AUC of 0.9449 for miR-18a.

healthy volunteers (mean): 16.36 vs 13.46 vs 0.73  $\text{amol } \mu\text{l}^{-1}$ ; Figures 3A and B). The values of AUC used to detect early ESCC such as pTis-1 and pStage0-I were 0.9479 and 0.9642, respectively. The diagnostic sensitivity, specificity, and accuracy of early ESCC

at the cutoff value of 1.99  $\text{amol } \mu\text{l}^{-1}$  using ROC curves were 88.1%, 100%, and 94.8% in pT0-1 or 96.7%, 100%, and 98.8% in pStage0-I, respectively (Figures 3A and B). Indeed, the sensitivity of plasma miR-18a for ESCC detection was much higher than that of

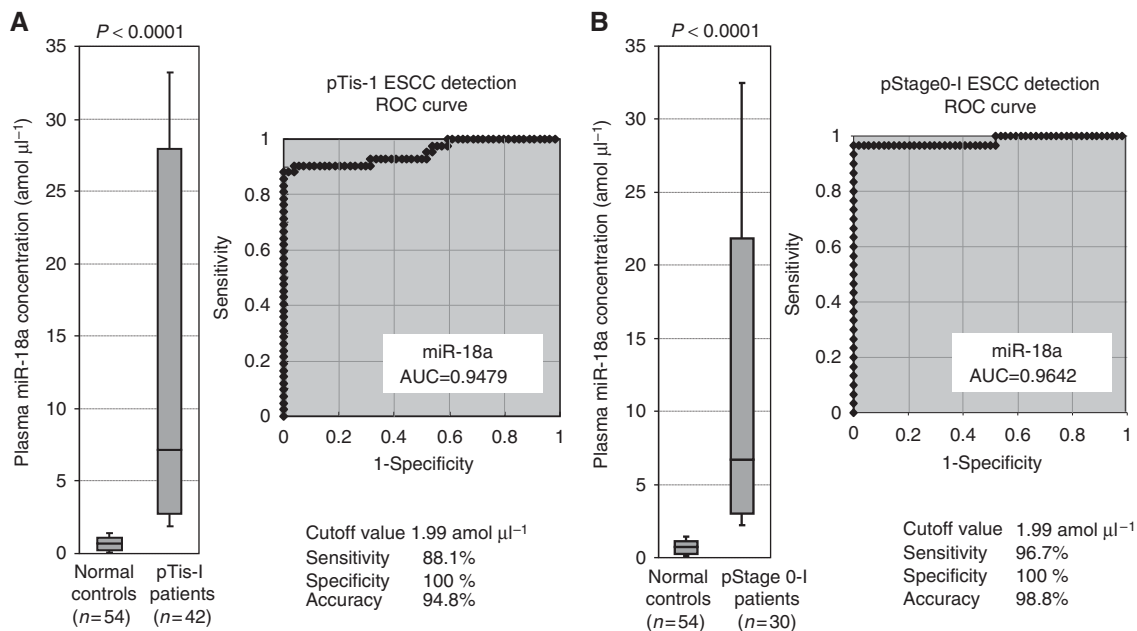

Figure 3. (A) Plasma miR-18a concentrations in 42 pathological Tis-T1 ESCC patients and 54 healthy volunteers. Concentrations of miR-18a were significantly higher in plasma from pathological Tis-T1 ESCC patients than in healthy volunteers ( $P < 0.0001$ ). The value of AUC to detect pTis-1 ESCC was 0.9479. (B) Plasma miR-18a concentrations in 30 pathological Stage0-1 ESCC patients and 54 healthy volunteers. Concentrations of miR-18a were significantly higher in plasma from pathological Stage0-1 ESCC patients than in healthy volunteers ( $P < 0.0001$ ). The value of AUC to detect pTis-1 ESCC was 0.9642.

conventional tumour markers including SCC, CEA, and SYFRA at our institute (pT0-1: SCC, CEA, and SYFRA: 25.0%, 21.1%, and 12.5%; pStage0-I: SCC, CEA, and SYFRA: 24.1%, 25.0%, and 3.4%; details not shown). Our results provided evidence that plasma levels of miR-18a can be used to distinguish early ESCC patients from healthy volunteers to a clinically satisfactory degree of sensitivity and specificity.

Also, we examined the association of plasma miR-18a concentrations with clinicopathological factors in 106 consecutive ESCC patients. Table 1 shows expression levels of miR-18a in plasma. However, we cannot present any significant correlations between the miR-18a level and clinical factors.

**Evaluation of the use of this assay for monitoring tumour dynamics in patients with ESCC.** We divided ESCC patients into two groups with high or low plasma miR-18a concentrations. We utilised a cutoff value of 1.99 amol  $\mu\text{l}^{-1}$ , which is the plasma miR-18a concentration detected by ROC curves using the Youden index to distinguish ESCC patients from healthy volunteers. To clarify the correlation of miR-18a expression between plasma and ESCC tissue, we selected 13 patients with high plasma miR-18a concentrations and compared miR-18a expression between plasma and ESCC tissues in each patient. As a result, in all high plasma miR-18a concentration patients analysed, miR-18a showed higher expression in primary ESCC tissues (100%) than the cutoff value of 1.66 for the tissue miR-18a/U6B ratio based on the mean value + 2 s.d. in normal oesophageal tissues (Supplementary Table 1). Moreover, the concentration of miR-18a was analysed in paired pre- and postoperative plasma samples from ESCC patients who underwent curative oesophagectomy, and was found to be significantly reduced in postoperative samples ( $P = 0.0076$ ; Figure 4A). These findings indicated that the level of miR-18a in plasma might reflect the expression in the tumour. In one patient, re-elevation of plasma miR-18a concentration was found at haematogenous recurrence after surgery (Figure 4B). Solitary liver metastasis, whose tumour size was 5 cm diameter, was detected at

6 months after curative oesophagectomy. These results clearly showed that detection of miR-18a in plasma should provide a new complementary tumour marker for ESCC.

**Correlation between plasma miR-18a concentrations and the haematocytes of peripheral blood.** A recent report demonstrated that some circulating miRNAs may be derived from peripheral blood cells (Pritchard *et al*, 2011). Therefore, we determined the correlation between plasma miR-18a concentrations and the haematocytes of peripheral blood in 106 ESCC patients. The results showed that there was no significant correlation between plasma miR-18a concentrations and any type of haematocyte in peripheral blood (Figure 5). Therefore, these findings imply that plasma miR-18a may not be derived from any type of haematocyte.

## DISCUSSION

During the last decade, non-coding RNAs, so-called miRNAs, have been demonstrated to regulate gene expression by targeting mRNAs for translational repression or cleavage. MicroRNAs have recently been proven to contribute to carcinogenesis and the progression of various cancer tumours and may provide new therapeutic strategies such as biomarkers and therapeutic targets for cancers (He *et al*, 2005; Lu *et al*, 2005; Calin and Croce, 2006; He *et al*, 2007). Furthermore, miRNAs were demonstrated to be present in a remarkably stable form in plasma/serum and the expression level of serum/plasma miRNAs is reproducible and consistent among individuals (Chen *et al*, 2008; Mitchell *et al*, 2008). In fact, accumulating reports have suggested that the presence of circulating miRNAs and their potential use as novel biomarkers for cancers, such as prostate cancer (Mitchell *et al*, 2008), leukemia (Lawrie *et al*, 2008), oral cancer (Wong *et al*, 2008), pancreatic cancer (Wong *et al*, 2008; Morimura *et al*, 2011), colorectal cancer (Wang *et al*, 2009), lung cancer (Hu *et al*, 2010),

Figure 4. **(A)** Comparison of plasma miR-18a concentrations between pre- and postoperative samples from ESCC patients. Concentrations of plasma miR-18a were significantly lower in postoperative samples compared than those in preoperative samples ( $P=0.0076$ ). **(B)** In one patient, re-elevation of plasma miR-18a concentrations was found at recurrence after surgery.

breast cancer (Heneghan *et al*, 2010), and gastric cancer (Tsujiura *et al*, 2010; Konishi *et al*, 2012).

Concerning ESCC, there have been only two reports on the role of circulating miRNAs in plasma/serum patients with ESCC (Zhang *et al*, 2010; Komatsu *et al*, 2011). Zhang investigated serum miRNA profiles in patients with ESCC using Solexa sequencing. Among 25 selected candidate miRNAs analysed, they identified seven serum miRNAs (miR-10a, 22, 100, 148b, 223, 133a, and 127-3p) as ESCC biomarkers. The area under the ROC curve for selected miRNAs ranged from 0.817 to 0.949. The AUCs using ROC curves for selected miRNAs were higher than for conventional serum tumour markers. Also, we analysed several candidate miRNAs in plasma of patients with ESCC, whose expression analyses are frequently reported in SCC tissues (Chang *et al*, 2008;

Avisar *et al*, 2009). As a result, miR-21 and miR-375 were stably detectable in plasma and reflected tumour dynamics as a tumour marker for ESCC (Komatsu *et al*, 2011). Moreover, concentrations of plasma miR-21 were significantly lower in postoperative samples than those in preoperative samples, and re-elevation of plasma miR-21 concentrations were found at recurrence after surgery despite the lack of an increase in conventional serum tumour markers. These findings could open up a new and promising field in the screening and monitoring of ESCC. However, these reports did not always warrant that these miRNAs were only candidate biomarkers for ESCC. Therefore, more sensitive and promising candidate miRNAs should be detected in clinical settings.

In this study, we tested miR-18a, which was located in the miR-17-92 cluster and was previously reported to be highly expressed in

the tissues of SCC (Chang *et al*, 2008; Avissar *et al*, 2009; Gao *et al*, 2011; Liu *et al*, 2011), as a new candidate miRNA in the plasma of patients with ESCC. miR-18a was expressed as part of the miR-17-92 cluster, which consists of seven miRNAs: miR-17-3p, miR-17-5p, miR-18a, miR-19a, miR-19b, miR-20a, and miR-92a. This cluster has been reported to have a potential oncogenic function in various tumours, with elevations in this cluster being caused by genome amplification or transcriptional activation by MYC (Woods *et al*, 2007). miR-18a has been shown to be significantly upregulated in gastric cancer (Yao *et al*, 2009), diffuse large B-cell lymphoma (Alencar *et al*, 2011), urothelial carcinomas of the bladder (Ayala de la Pena *et al*, 2011), nasopharyngeal carcinoma (Li *et al*, 2011), hepatocellular carcinoma, pancreatic carcinoma, and colorectal carcinomas (Motoyama *et al*, 2009). In colorectal cancer tissues, patients with overexpressed miR-18a had a poorer clinical prognosis. Also, miR-18a was confirmed to directly target ER- $\alpha$  and showed higher levels of expression in ER- $\alpha$ -negative clinical tumours (Leivonen *et al*, 2009). Interestingly, miR-18a had a proliferative effect on hepatocellular carcinoma cells, but an inhibitory effect on breast cancer cells (Leivonen *et al*, 2009).

Previously, we reported that the presence of markedly elevated miR-18a levels in plasma could provide new complementary tumour markers for pancreatic cancer (Morimura *et al*, 2011). Namely, plasma concentrations of miR-18a were significantly higher in pancreatic cancer patients than in controls. The value of the area under the ROC curve (AUC) was 0.9369. Therefore, we hypothesised that miR-18a may also be a useful biomarker in the plasma of patients with ESCC. As a result, we confirmed that expression of miR-18a was significantly higher in ESCC tissues and ESCC cell lines than normal tissues and fibroblasts. Plasma concentrations of miR-18a were significantly higher in ESCC patients than controls. The AUC was 0.9449, which was markedly higher than other miRNAs in plasma of cancer patients (Tsujiura *et al*, 2010; Komatsu *et al*, 2011; Morimura *et al*, 2011; Konishi *et al*, 2012). Furthermore, the ROC curve used to detect early ESCC such as pTis-1 or pStage0-I showed an AUC of 0.9479 or 0.9642, respectively, suggesting that plasma miR-18a concentrations may be a useful biomarker for the detection of ESCC.

Next, we investigated whether plasma miR-18a concentrations could reflect tumour dynamics in ESCC by three different analyses. One is the comparison between expression of miR-18a in plasma and primary tumour tissue, which demonstrated that plasma and primary ESCC tissue samples showed that high levels of plasma miR-18a represented higher expressions in primary ESCC tissues than in normal mucosa in all patients analysed (100%) (Supplementary Table 1). Some patients, however, showed a different pattern of miRNA levels, low plasma miR-18a with a high expression in ESCC tissue (data not shown). The reasons for these discrepancies in some patients remain to be identified; however, one possible explanation for this finding is the heterogeneity of primary tumours. Second analysis involves comparison of plasma miR-18a concentrations in paired plasma obtained before and after surgery. As a result, concentrations of miR-18a were significantly reduced postoperatively in patients with high preoperative plasma miR-18a (Figure 4A). These findings were similar to those in patients with ESCC, gastric, and pancreatic cancer in our previous report (Tsujiura *et al*, 2010; Komatsu *et al*, 2011; Morimura *et al*, 2011; Konishi *et al*, 2012). Third analysis was to determine that re-elevation of plasma miR-18a concentrations were found at recurrence after surgery even in one ESCC patient as well as our previous reports (Komatsu *et al*, 2011; Morimura *et al*, 2011) (Figure 4B). These findings clearly demonstrated that plasma concentrations of miR-18a reflect tumour dynamics and are available as a new plasma biomarker for monitoring tumour status such as residue and recurrence of ESCC.

Recently, Pritchard CC, Tewari M, and his colleagues reported the caution in a cancer biomarker study of circulating miRNAs

because circulating miRNAs may be derived from peripheral blood cells (Pritchard *et al*, 2011). Therefore, we evaluated the correlation between plasma miR-18a concentrations and haematocytes of peripheral blood in 106 consecutive ESCC patients. As a result, there was no significant association between plasma miR-18a concentrations and any types of peripheral haematocyte (Figure 5). This result indicated that miR-18a expression in plasma may reflect tumour dynamics in ESCC patients. However, as secretion, kinetics, and metabolism in plasma miRNAs have not been clearly elucidated, this issue is currently under evaluation.

Taken together, we clearly demonstrated that plasma levels of miR-18a may potentially be useful for cancer screening and monitoring tumour dynamics in ESCC patients postoperatively. Nevertheless, many issues must be addressed before these findings can be translated into a clinically useful, non-invasive screening strategy for ESCC patients. We will prospectively confirm the usefulness of plasma miR-18a in a large number of patients and report on these results in the near future. Furthermore, if possible, more sensitive biomarkers in plasma miRNAs should be detected for translation into the clinical setting of ESCC. These issues are also currently under evaluation in an array-based study using large candidate numbers of miRNA and will be reported in the near future.
