Proteins in the PYR/PYL/RCAR family (PYLs) are known as receptors for the phytohormone ABA. Upon ABA binding, PYL adopts a conformation that allows it to interact with and inhibit clade A protein phosphatase 2Cs (PP2Cs), which are known as the co-receptors for ABA. Inhibition of the PP2Cs then leads to the activation of the SnRK2 family protein kinases that phosphorylate and activate downstream effectors in ABA response pathways. The PYL family has 14 members in *Arabidopsis*, 13 of which have been demonstrated to function as ABA receptors. The function of PYL13, a divergent member of the family, has been enigmatic. We report here that PYL13 differs from the other PYLs in three key residues that affect ABA perception, and mutations in these three residues can convert PYL13 into a partially functional ABA receptor. Transgenic plants overexpressing *PYL13* show increased ABA sensitivity in seed germination and postgermination seedling establishment as well as decreased stomatal conductance, increased water-use efficiency, accelerated stress-responsive gene expression, and enhanced drought resistance. *pyl13* mutant plants are less sensitive to ABA inhibition of postgermination seedling establishment. PYL13 interacts with and inhibits some members of clade A PP2Cs (PP2CA in particular) in an ABA-independent manner. PYL13 also interacts with the other PYLs and antagonizes their function as ABA receptors. Our results show that PYL13 is not an ABA receptor but can modulate the ABA pathway by interacting with and inhibiting both the PYL receptors and the PP2C co-receptors.

## Introduction

ABA is an important phytohormone that participates in plant abiotic stress signaling [1]. The PYR/PYL/RCAR family proteins (hereafter referred to as PYLs) are ABA receptors in the cytoplasm and nucleus [2-5]. The PYL family has 14 members in *Arabidopsis*, including PYR1 and PYLs 1-13, each containing a START

domain. Several of the PYLs have been shown to bind and inhibit clade A protein phosphatase type 2Cs (PP2Cs, comprising ABI1, ABI2, HAB1, HAB2, AHG1, PP2CA, HAI1, HAI2, and HAI3) in the presence of ABA [2-4, 6, 7]. Structural studies confirmed that the PYLs are ABA receptors and showed that the PP2Cs can function as co-receptors because they enhance the ABA-binding affinities of the PYLs [5, 8-11]. In *Arabidopsis* protoplasts, PYR1 and PYLs 1-12 could release ABI1 inhibition of ABA-dependent activation of *RD29B-LUC* expression by the SnRK2 protein kinases such as OST1/SnRK2.6 [4]. Structural analysis revealed that the interaction between SnRK2.6 and HAB1 mimics the interaction between ABA-bound PYL2 and HAB1 [12]. PYLs can inhibit

PP2C activity in the presence of ABA, and thereby activating SnRK2.6, which can phosphorylate slow anion channel1 (SLAC1) and activate SLAC1-mediated ion currents [13, 14].

PYLs have an ABA-binding pocket that comprises four highly conserved regions named CLs 1-4 [8]. The structure of PYL changes after ABA binding [5, 8-10], allowing the formation of an ABA-PYL-PP2C complex and the inhibition of PP2Cs, thus releasing the inhibition of SnRK2.2/2.3/2.6 by clade A PP2Cs [15, 16]. SnRK2.2/2.3/2.6 are positive regulators of ABA signaling [17-19]. Activated SnRK2.2/2.3/2.6 can phosphorylate and activate transcription factors such as ABFs/AREBs [20, 21] to induce the expression of ABA-responsive genes such as *RD29B* [4]. In guard cells, the SnRK2s can also phosphorylate and activate the NADPH oxidase catalytic subunit RBOHF, leading to the production of reactive oxygen species (ROS) [17, 22, 23]. SnRK2s also interact with and phosphorylate plasma membrane anion channels such as SLAC1 to regulate ion transport [13, 24-26].

Many monomeric PYL proteins may also interact with certain PP2Cs in an ABA-independent manner in yeast two-hybrid assays and pull-down assays [2, 27]. However, this interaction is weak and in the particular case of PYL10-ABI1 interaction, the dissociation constant (*K<sub>d</sub>*) changed from 1.2  $\mu$ M without ABA to 0.02  $\mu$ M with ABA [27], indicating that the interaction between PYL10 and ABI1 is enhanced by ABA. *In vitro* assays demonstrated that PYL10 shows obvious ABA-independent inhibition of ABI1, HAB1, and HAB2 with a PYL:PP2C ratio of 1:1, and PYLs 5-10 (except the untested PYL7) shows ABA-independent inhibition of ABI1, HAB1, HAB2, and PP2CA to different degrees with the PYL:PP2C ratio of 10:1 and 100:1 [27]. However, the ABA-independent inhibitions are much weaker than the ABA-dependent ones.

Although the PYL family proteins have been studied intensively in recent years [6, 28-31], little information is available for PYL13, which differs from other PYLs in the highly conserved regions of their ABA-binding pocket. To study the function of PYL13, we examined the interaction of PYL13 with clade A PP2Cs and the effects of PYL13 on the PP2Cs both *in vitro* and *in vivo*. We found that PYL13 can bind to the PP2Cs and in particular can constitutively inhibit PP2CA in an ABA-independent manner. Very interestingly, PYL13 interacts with the other PYLs and can reduce the ability of other PYLs to inhibit PP2Cs. Transgenic plants overexpressing PYL13 exhibit improved drought resistance and increased sensitivity to ABA inhibition of germination and postgermination seedling establishment while *pyl13* mutant plants are

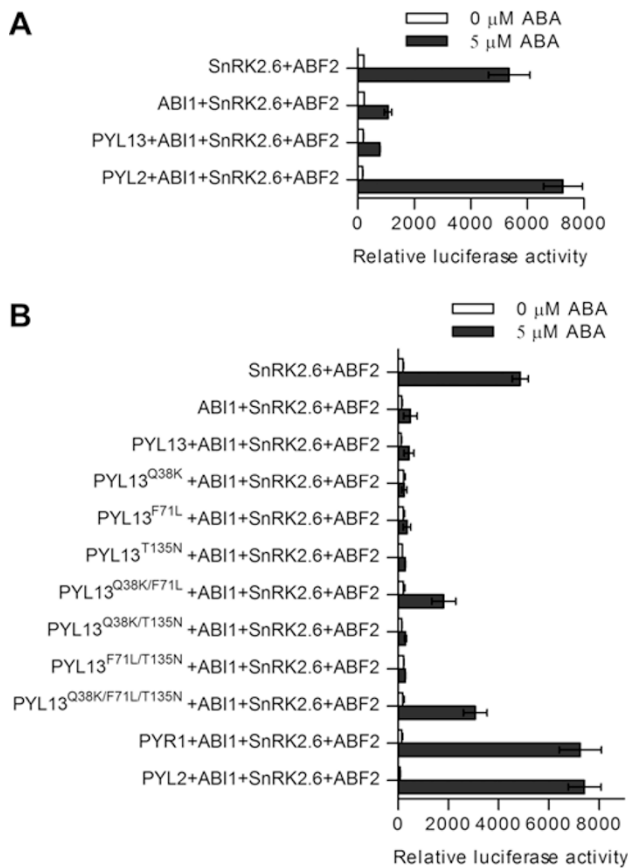

less sensitive to ABA inhibition of postgermination seedling establishment, indicating that PYL13 is functionally important *in planta*.

## Results

### *PYL13 differs from the other PYLs and does not function as an ABA receptor*

The PYL family contains 14 members. Although previous studies suggested that many are ABA receptors and have redundancy [2, 31], they also showed functional differences [6, 27]. In the presence of ABA, PYR1 and PYLs 1-12 reduced the activity of ABI1 and activated SnRK2.6 to induce *RD29B-LUC* expression in *Arabidopsis* mesophyll protoplasts [4]. To test whether PYL13 can act as an ABA receptor, we reconstituted the ABA signaling pathway in wild-type (WT) protoplasts. As expected, the addition of PYL2 inhibited ABI1 activity and enabled the expression of ABA-dependent induction of *RD29B-LUC* (Figure 1A). However, co-transfection of PYL13 with ABI1, SnRK2.6, and ABF2 did not enable the expression of *RD29B-LUC* (Figure 1A). The results suggest that PYL13 is a unique member of the PYL family and cannot function as an ABA receptor.

As noted earlier, the ABA-binding pocket in PYLs consists of four highly conserved regions named CLs 1-4 [8]. Amino acid sequence alignment shows that PYL13 differs from other PYLs in key residues in CLs 1-2 and CL4 (Q38 in CL1, F71 in CL2, and T135 in CL4; Supplementary information, Figure S1). To test whether these sequence variations may explain the functional difference of PYL13, we introduced point mutations (Q38K, F71L and T135N) to PYL13 to mimic the other PYLs, and transfected these mutated PYL13 together with ABI1, SnRK2.6, and ABF2 into protoplasts. None of the single mutations in PYL13 could mimic PYR1 in elevating the *RD29B-LUC* expression. Double mutations (Q38K/F71L), and triple mutations (Q38K/F71L/T135N) of PYL13 could partially confer an ABA-dependent induction of *RD29B-LUC* expression (Figure 1B). Q38 and F71 in CLs 1-2 appear to be the most important residues because PYL13 with these two residues mutated became largely functional in the reconstitution assay. The T135N mutation in CL4 could enhance the ability of PYL13 mutants to inhibit ABI1 activity in the presence of ABA. These results suggest that the inability of PYL13 to act as an ABA receptor is partially attributed to the three amino acid variations (Q38 in CL1, F71 in CL2, and T135 in CL4). However, as triple mutations (Q38K/F71L/T135N) of PYL13 cannot be as effective as PYR1 and PYL2 in inducing *RD29B-LUC* expression, other sequence variations may also contribute to the inability of PYL13 to act

**Figure 1** PYL13 differs from other PYLs. **(A)** PYL13 cannot antagonize the ability of ABI1 to inhibit the ABA-dependent induction of *RD29B-LUC* expression in protoplasts. The ABA signaling pathway was reconstituted by co-expression of PYLs, ABI1, SnRK2.6, and ABF2. **(B)** PYL13 mutants can mimic PYR1/PYL2 in elevating the expression of *RD29B-LUC* in protoplasts. WT Col-0 protoplasts were used in both **A** and **B**. *RD29B-LUC* was used as the ABA-responsive reporter. *ZmUBQ-GUS* was used as the internal control. After transfection, protoplasts were incubated for 4.5 h under light in the absence of ABA (open bars) or in the presence of 5 μM ABA (closed bars). Error bars indicate SEM ( $n = 3$ ).

fully as an ABA receptor.

*Overexpression of PYL13 confers drought resistance in Arabidopsis*

Previous studies showed that overexpression of PYL5 leads to an enhanced response to ABA and drought resistance [32]. Given that PYL13 does not function as an ABA receptor, we wonder whether it may still have a function in plants. We generated *PYL13* overexpression (*OE-PYL13*) lines, and chose three homozygous T3 lines for phenotypic analysis. Northern blot analysis indicated

that *PYL13* transcripts were obviously more abundant in *OE-PYL13* lines than in WT (Supplementary information, Figure S2).

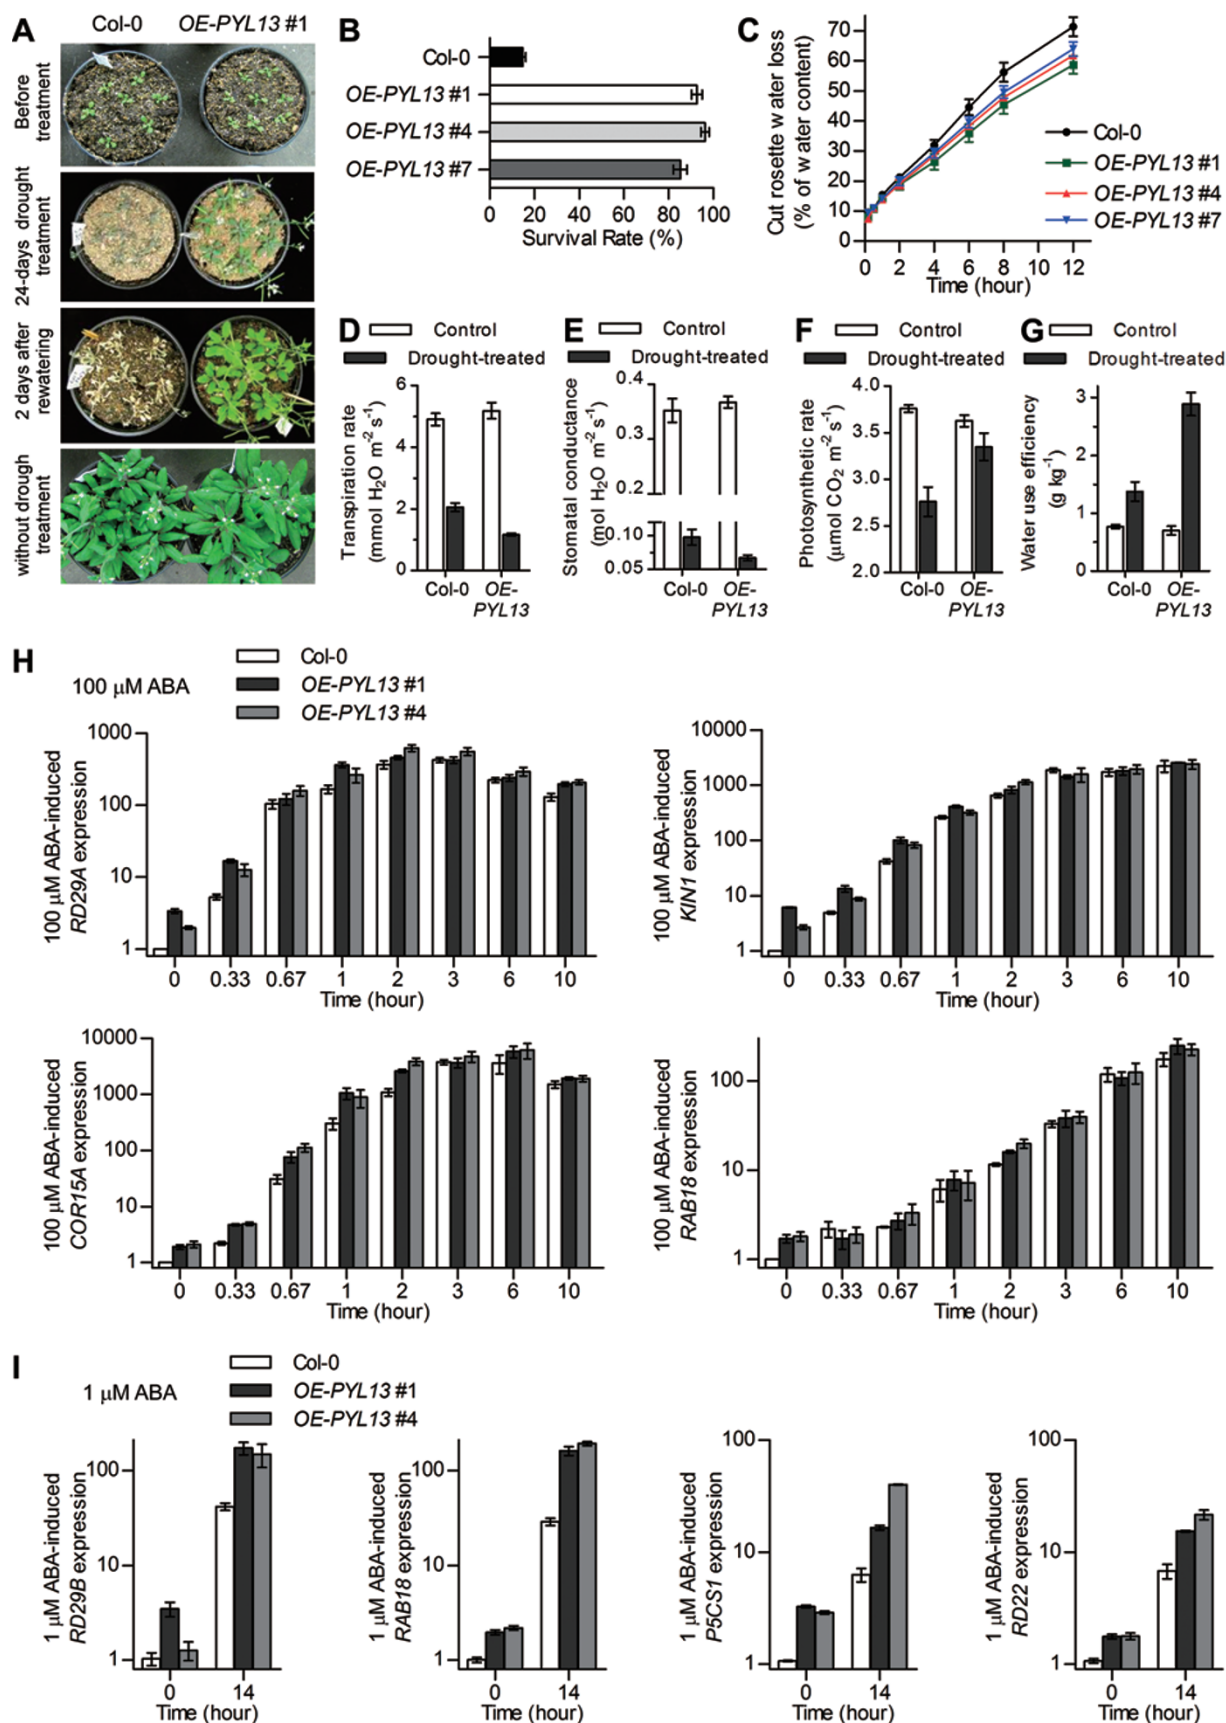

*OE-PYL13* lines exhibited an improved drought resistance (Figure 2A). After a 24-day drought treatment in soil, > 80% of *OE-PYL13* transgenic plants survived and < 20% of WT plants survived (Figure 2B). The greater survival under drought stress of *OE-PYL13* lines was associated with reduced water loss from leaves of the *OE-PYL13* lines. Water loss from rosette leaves detached at the same developmental stage was slower in *OE-PYL13* lines than in WT (Figure 2C). To characterize the drought resistance in *OE-PYL13* transgenic plants, we determined several physiological parameters. When water was withheld for 5 days, transgenic plants overexpressing *PYL13* showed a lower transpiration rate than WT plants (Figure 2D) and this was accompanied with a reduced stomatal conductance (Figure 2E). The photosynthetic rate (Figure 2F) and water-use efficiency (Figure 2G) were greater in *OE-PYL13* lines than in WT. These results demonstrate that overexpression of *PYL13* confers drought resistance in *Arabidopsis*.

*Overexpression of PYL13 promotes stress-responsive gene expression*

To further characterize the *PYL13* overexpression lines, we tested the expression of stress-responsive genes including *RD29A*, *KINI*, *COR15A*, and *RAB18* in the transgenic plants (Figure 2H). Under the unstressed control condition, the transcript levels of the four tested stress-responsive genes were 2-6-fold higher in the *OE-PYL13* lines than in WT Col-0. Expression of *RD29A*, *KINI*, *COR15A*, and *RAB18* was induced by ABA treatment in the *OE-PYL13* transgenic lines as well as in Col-0. However, the levels of *RD29A*, *KINI*, and *COR15A* were higher in *OE-PYL13* seedlings than in Col-0 seedlings at early time points (e.g., 20 and 40 min) after ABA treatment. At later time points (e.g., 6 h), the levels of *RD29A*, *KINI*, *COR15A*, and *RAB18* in *OE-PYL13* seedlings were similar to those in Col-0 seedlings.

We also tested the expression of stress-responsive genes in *PYL13* overexpression lines under a lower concentration of ABA. Expression of *RD29B*, *RAB18*, *P5CS1*, and *RD22* was induced by 1 μM ABA treatment both in the *OE-PYL13* transgenic lines and in Col-0 WT plants (Figure 2I), while the expression of *RD29A*, *KINI*, and *COR15A* was not obviously induced by 1 μM ABA treatment (data not shown). After 14 h treatment with 1 μM ABA, the transcript levels of *RD29B*, *RAB18*, *P5CS1*, and *RD22* were 2-7-fold higher in the *OE-PYL13* lines than in the Col-0 WT plants.

Taken together, these results suggested that overex-

**Figure 2** Overexpression of PYL13 confers drought resistance. **(A)** Fourteen-day-old plants were subjected to drought stress treatment (water was withheld for 24 days) before watering was resumed. Representative photographs show plants before drought treatment, after drought treatment, and without drought treatment. For the “after drought treatment”, plants were also photographed 2 days after watering was resumed. **(B)** Surviving plants were counted 2 days after watering was resumed. Error bars indicate SEM ( $n = 3$ ). **(C)** Cumulative transpirational water loss from rosettes of the WT Col-0 and *PYL13* overexpression (*OE-PYL13*) lines at the indicated times after detachment. Error bars indicate SEM ( $n = 3$ ). **(D–G)** Physiological parameters of *OE-PYL13* lines under drought-stress conditions. Three-week-old plants were subjected to drought stress (water was withheld for 5 days) before parameters were measured with an infrared gas analyzer. Overexpression of *PYL13* reduced the transpiration rate **(D)**, reduced stomatal conductance **(E)**, increased the photosynthetic rate **(F)**, and increased water-use efficiency **(G)**. *OE-PYL13* values are the means of three independent transgenic lines. Error bars indicate SEM ( $n = 4$ ). **(H)** Expression of stress-responsive genes in *OE-PYL13* lines. Quantitative RT-PCR was conducted on 10-day-old seedlings with 100  $\mu$ M ABA treatment for 0 min, 20 min, 40 min, 1 h, 2 h, 3 h, 6 h, and 10 h. The expression levels of *RD29A*, *KIN1*, *COR15A* and *RAB18* in Col-0 before ABA treatment were set as 1. Error bars indicate SEM ( $n = 3$ ). **(I)** Expression of stress-responsive genes in *OE-PYL13* lines. Quantitative RT-PCR was conducted on 10-day-old seedlings with 1  $\mu$ M ABA treatment for 14 h. The expression levels of *RD29B*, *RAB18*, *P5CS1* and *RD22* in Col-0 before ABA treatment were set as 1. Error bars indicate SEM ( $n = 3$ ).

pression of *PYL13* enhances stress-responsive gene expression in plants.

#### *PYL13* interacts with clade A PP2Cs in an ABA-independent manner

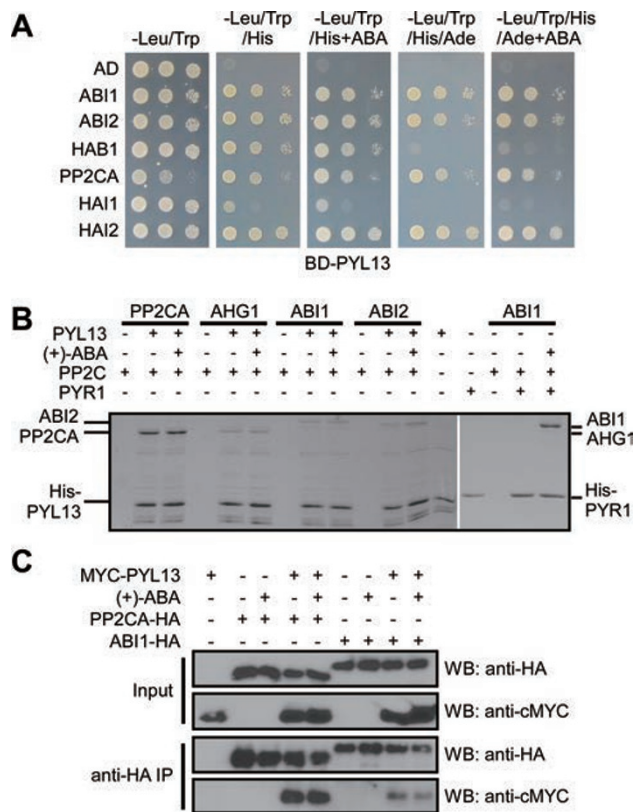

To investigate how *PYL13* may function in plants, we examined the interaction between *PYL13* and clade A PP2Cs in yeast two-hybrid assays. The results show that *PYL13* binds to all PP2Cs tested in an ABA-independent manner (Figure 3A). *PYL13* binds strongly with ABI1, ABI2, PP2CA, and HAI2 but weakly with HAB1 and HAI1 (Figure 3A). We confirmed these results in pull-down assays with purified recombinant proteins, in which *PYL13* interacted with all PP2Cs tested in an ABA-independent manner while *PYR1* interacted with ABI1 in an ABA-dependent manner (Figure 3B). In the pull-down assay, *PYL13* binding was much stronger with PP2CA than with AHG1, ABI1, or ABI2 (Figure 3B). To determine whether *PYL13* and PP2Cs may interact in an ABA-independent manner *in vivo*, we co-expressed c-myc-tagged *PYL13* and hemagglutinin (HA)-tagged PP2Cs in protoplasts. Co-immunoprecipitation (co-IP) assays using ABI1-HA and PP2CA-HA as baits captured c-myc-*PYL13* in an ABA-independent manner (Figure 3C). The binding of PP2CA with *PYL13* again appeared much stronger than that of ABI1 with *PYL13*. These results demonstrated that *PYL13* constitutively binds to clade A PP2Cs, but the binding intensity differs among members of clade A PP2Cs.

#### *PYL13* differentially inhibits clade A PP2Cs in an ABA-independent manner and is important for seed germination

*PYL13* interacts with all members of clade A PP2Cs tested but binds most strongly to PP2CA (Figure 3). To

investigate whether *PYL13* inhibits PP2Cs *in planta*, we co-expressed *PYL13* with all clade A PP2Cs in WT protoplasts. Transfections of all PP2Cs together with SnRK2.6 and ABF2 inhibited *RD29B-LUC* expression to different degrees (Figure 4A), and the degree of inhibition was correlated with the intensity of interaction between PP2Cs and SnRK2.6 [4]. For example, the intensities of PP2C interaction with SnRK2.6 were ABI1>HAB1>ABI2 in yeast two-hybrid assays, and the inhibition of *RD29B-LUC* expression was greater for ABI1 than HAB1 and was greater for HAB1 than for ABI2 in the protoplast experiments (Figure 4A). Co-transfections of *PYL13* together with ABI1, ABI2, HAB1, HAB2, or AHG1 did not enable *RD29B-LUC* expression, but co-transfections of *PYL13* with PP2CA, HAI2, or HAI3 enabled the ABA-dependent induction of *RD29B-LUC* expression (Figure 4A). In the control experiments, co-transfections of *PYR1* and *PYL2* with ABI1 restored ABA-induced *RD29B-LUC* expression (Figure 4A). These results indicated that *PYL13* inhibits the phosphatase activities of PP2CA, HAI2, and HAI3. The ABA responsiveness of the *PYL13*-transfected protoplasts as well as of the protoplasts without any transfected PYLs was presumably due to the activities of endogenous PYLs present in the protoplasts.

To investigate the underlying mechanism by which *PYL13* differentially inhibits the function of PP2Cs, we examined the effects of recombinant *PYL13* on the phosphatase activities of recombinant PP2Cs with and without ABA. The results showed that *PYL13* acts as a strong constitutive inhibitor of PP2CA phosphatase activity and a weak inhibitor of ABI1 activity but has almost no inhibitory activity against ABI2 at the molar ratio of 1:1 (Figure 4B). The inhibition by *PYL13* is ABA-independent, whereas the inhibition by *PYR1* and *PYL2*

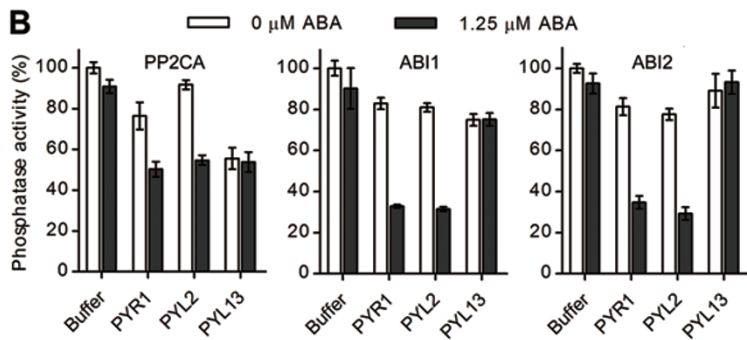

**Figure 3** PYL13 binds to clade A PP2Cs in an ABA-independent manner. **(A)** PYL13 interacts with clade A PP2Cs in a yeast two-hybrid assay. PYL13 fused to the GAL4-DNA-binding domain (BD) was used as prey, and PP2Cs fused to the GAL4-activating domain (AD) were used as baits. The interaction was determined by growth assay on media lacking His and His/Ade in the presence and absence of 10  $\mu$ M ABA. Dilutions ( $10^{-1}$ ,  $10^{-2}$ , and  $10^{-3}$ ) of saturated cultures were spotted onto the plates, which were photographed after 5 days. **(B)** Recombinant PYL13 binds to clade A PP2Cs in an ABA-independent manner. His-tagged PYL13 (~22 kD) and PYR1 (~25 kD) were used to pull down PP2Cs without tag. PYL13 interacted with PP2CA, AHG1, ABI1 and ABI2 independent of ABA while PYR1 interacted with ABI1 in the presence of 200  $\mu$ M ABA. **(C)** ABA-independent binding of PYL13 with PP2CA and ABI1 in protoplasts. Total soluble proteins (input) were extracted from *Arabidopsis* protoplasts that transiently expressed the indicated constructs. PP2C-interacting proteins were immunoprecipitated with anti-HA mouse antibodies and detected with anti-HA and anti-cMYC rabbit antibodies.

is ABA-induced (Figure 4B). PYL13 reduced PP2CA phosphatase activity to  $55\% \pm 5\%$  without ABA and to  $54\% \pm 5\%$  with 1.25  $\mu$ M ABA, and reduced ABI1 phosphatase activity to  $75\% \pm 3\%$  without ABA and to  $75\% \pm 3\%$  with 1.25  $\mu$ M ABA. In contrast, PYL13 only reduced ABI2 phosphatase activity to  $89\% \pm 8\%$  without ABA and to  $93\% \pm 6\%$  with 1.25  $\mu$ M ABA, and this level of

activity did not differ from that in the buffer control with ABA ( $93\% \pm 5\%$ ). These results show that PYL13 differentially inhibits the phosphatase activities of PP2Cs in an ABA-independent manner.

We observed that the basal *RD29B-LUC* expression level was elevated in protoplasts co-transfected with PP2CA-PYL13, HAI2-PYL13, or HAI3-PYL13, which is consistent with PYL13 inhibition of these PP2Cs in an ABA-independent manner *in vivo* (Figure 4A). To exclude interference by endogenous PP2Cs in WT protoplasts and to assess the ABA-independent selective inhibition of PP2Cs by PYL13, we co-expressed PYL13 with PP2CA, HAI1, HAI2, and HAI3 in *abi1/hab1/abi2* triple mutant protoplasts. This mutant is deficient in ABI1, HAB1, and ABI2 but does not show strong constitutive activation of SnRK2.2/2.3/2.6 [4, 33]. Expression of *RD29B-LUC* in the absence of ABA was increased in the co-transfections of PP2CA-PYL13, HAI2-PYL13, or HAI3-PYL13 together with SnRK2.6 and ABF2 but an increase was not observed in the control transfections of PYL13-HAI1 or PYL2-PP2CA (Figure 4C). The triple mutation Q38K/F71L/T135N abolished the ability of PYL13 to elevate *RD29B-LUC* expression in the absence of ABA, indicating that the three amino acid variations are responsible for the ABA-independent inhibition of PP2Cs by PYL13 (Figure 4C). These data further suggested that PYL13 inhibits PP2CA, HAI2, and HAI3 in an ABA-independent manner *in vivo*.

Overexpression of *AtPP2CA* resulted in ABA insensitivity while knockout of *AtPP2CA* caused ABA hypersensitivity during seed germination [34]. Given the strong inhibition by PYL13 on PP2CA activity *in vitro* and *in vivo*, we investigated whether PP2CA function *in planta* may be impacted by PYL13 overexpression. We tested the seed germination of *PYL13* overexpression lines on MS medium containing 0, 0.5 or 1  $\mu$ M ABA. In the absence of exogenous ABA, *OE-PYL13* seeds germinated as well as WT seeds (Figure 4E, left panel). In the presence of 0.5  $\mu$ M ABA, the germination of *OE-PYL13* #1 was greatly inhibited by ABA (Figure 4E, middle panel). In the presence of 1  $\mu$ M ABA, ABA-hypersensitive inhibition of seed germination was observed for *OE-PYL13* #1 and *OE-PYL13* #7 (Figure 4E, right panel). Postgermination seedling establishment inhibition in the presence of 0.2  $\mu$ M ABA was observed for *OE-PYL13* #1 (Figure 4F). The germination sensitivity to ABA was correlated with the expression level of *PYL13* (Supplementary information, Figure S2). In contrast, *pyl13-1* (SALK\_041176) and *pyl13-2* (SALK\_071488) mutants (Figure 4D) were less sensitive to ABA inhibition of postgermination seedling establishment (Figure 4F) and showed no obvious phenotype upon ABA inhibition of

germination (Figure 4E).

*PYL13 interacts with and antagonizes other PYLs*

To further investigate the molecular mechanism of PYL13 function in plants, we generated transgenic *Arabidopsis* plants expressing tagged PYL13 under the native *PYL13* promoter (*ProPYL13: PYL13-HA-YFP*

(Supplementary information, Figure S3A) and purified PYL13-associated proteins using anti-GFP-agarose in extracts of floral organs of the transgenic plants (Supplementary information, Figure S3B). PYL13-associated proteins were identified by mass spectrometric analyses (Supplementary information, Table S1). The associated proteins included not only PP2CA and HAI1 but also

**Figure 4** PYL13 inhibits clade A PP2Cs in an ABA-independent manner. **(A)** Inhibition of *RD29B-LUC* expression by PP2CA, HAI2, and HAI3 was antagonized by PYL13 in WT protoplasts. ABA signaling pathway was reconstituted by co-expression of PYLs, PP2Cs, SnRK2.6, and ABF2. *RD29B-LUC* was used as the ABA-responsive reporter. *ZmUBQ-GUS* was used as the internal control. After transfection, protoplasts were incubated for 4.5 h under light in the absence of ABA (open bars) or in the presence of 5  $\mu$ M ABA (closed bars). Error bars indicate SEM ( $n = 9$ ). **(B)** The activities of recombinant clade A PP2Cs were differentially inhibited by recombinant PYL13 independently of ABA. The phosphatase activities of PP2CA, ABI1, and ABI2 were measured in the absence or presence of ABA (1.25  $\mu$ M), and with or without PYLs. The concentration of PP2Cs and PYLs was 0.3  $\mu$ M. The  $A_{405}$  value of reaction without PP2C was set as 0% and that of the reaction with PP2C but without ABA and PYLs was set as 100%. Error bars indicate SEM ( $n = 6$  for PP2CA and ABI2, and  $n = 3$  for ABI1). **(C)** ABA-independent induction of *RD29B-LUC* in *abi1/hab1/abi2* protoplasts that transiently expressed PYL13, PP2CA, HAI2, or HAI3. The two T-DNA insertions are also indicated. **(E)** Seed germination of the WT, *pyl13* mutants and *PYL13* overexpression (*OE-PYL13*) lines in MS medium and MS plus 0.5 or 1  $\mu$ M ABA. The panels show the percentage of seeds with emerged radicle. Error bars indicate SEM ( $n = 3$ ). **(F)** Seedling establishment of the WT, *pyl13* mutants and *OE-PYL13* transgenic line in MS medium and MS plus 0.2  $\mu$ M ABA. The panels show the percentage of seeds that developed green cotyledons. Error bars indicate SEM ( $n = 3$ ).

PYL2 and PYL9. While the result confirmed the interaction of PYL13 and PP2Cs *in planta* (Figure 3), it also raised the possibility of PYL13 interaction with and affecting the activities of other PYLs.

To confirm the interaction between PYL13 and PYL2/PYL9 and to determine whether PYL13 may bind with other PYLs, we examined the interaction of PYL13 with PYLs in yeast two-hybrid assays. In this experiment, PYL13 interacted with PYR1, PYLs 1-4, PYL6, and PYLs 11-12 in an ABA-independent manner (Figure 5A). These results thus confirmed the interaction between PYL13 and PYL2 identified in immunoprecipitation and mass spectrometric experiments. However, we were unable to detect an interaction between PYL13 and PYL9, perhaps due to the cellular differences between yeast and *Arabidopsis* or due to indirect interactions between the two proteins in *Arabidopsis*.

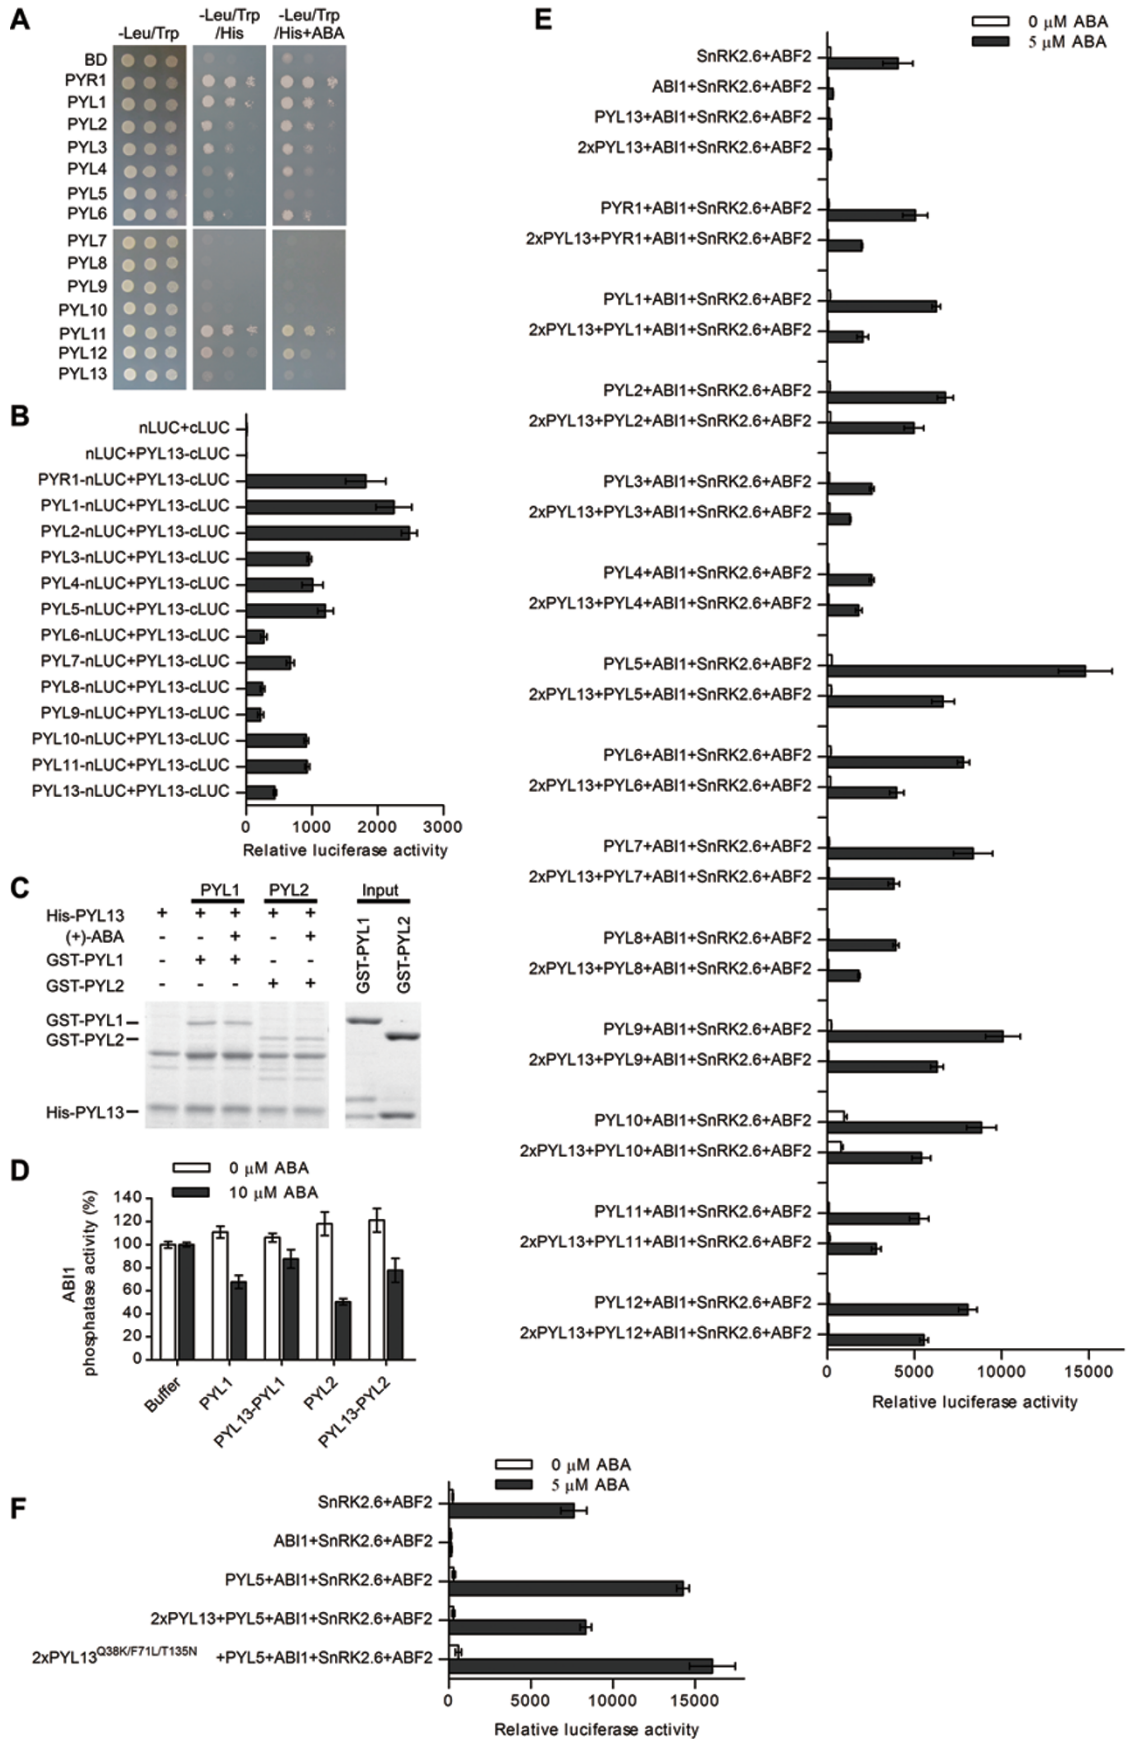

To further characterize the interactions between PYL13 and PYLs *in vivo*, we investigated their interactions in protoplasts by the firefly luciferase (LUC) complementation assay [35]. We fused PYL13 to the C-terminal domain of LUC (PYL13-cLUC), and fused PYLs to the N-terminal domain of LUC (PYLs-nLUC), and co-expressed them in protoplasts. The relative LUC activities were measured, and the results suggested that PYL13 binds to all PYLs tested but with different intensities (Figure 5B). PYL13 binds more strongly to PYR1, PYLs 1-5, PYL7, and PYLs 10-11 than to PYL6, PYLs 8-9, or PYL13 (Figure 5B). The direct interactions between PYL13 and two of the PYLs were also verified in pull-down assays with purified recombinant proteins. GST-tagged PYL1 (~51 kD) and PYL2 (~46 kD) were pulled down by His-tagged PYL13 (~22 kD) in an ABA-independent manner (Figure 5C). Previous structural and biochemical investigations demonstrated that several

PYLs (such as PYR1, PYL1, PYL2, PYL3) form homodimers in solution and that the dimer formation is important in regulating ABA binding and PP2C interactions [5, 8, 11, 27, 28, 36, 37]. Our results suggest that PYL13 can form heterodimers with other PYLs.

To test the functional significance of potential heterodimer formation between PYL13 and other PYLs, we compared the abilities of PYL1 and PYL2 and the protein complexes of PYL13-PYL1 and PYL13-PYL2 to inhibit the phosphatase activity of ABI1 using purified recombinant proteins and the synthetic phosphatase substrate p-nitrophenyl phosphate (pNPP). The results showed that inhibition of ABI1 in the presence of ABA was less for the PYL13-PYLs dimers than for the PYLs alone (Figure 5D). In the presence of 10  $\mu$ M ABA, ABI1 phosphatase activity was reduced to 67%  $\pm$  6% by PYL1 but only to 88%  $\pm$  8% by PYL13-PYL1, and was reduced to 50%  $\pm$  3% by PYL2 but only to 78%  $\pm$  10% by PYL13-PYL2. These results suggest that, by forming heterodimers, PYL13 can reduce the ability of PYL1 and PYL2 to inhibit the phosphatase activity of ABI1 *in vitro*.

To investigate the physiological significance of the binding between PYL13 and PYLs *in vivo*, we co-expressed PYL13 with one of the other PYLs, ABI1, SnRK2.6, and ABF2 in WT protoplasts. When the amount of transfected *PYL13* plasmid was 2-fold of that of the other *PYLs*, co-transfections with PYL13 decreased the activity of the ABA-responsive PYLs (Figure 5E). The level of inhibition by PYL13 depended on the PYLs and ranged from 27% with PYL2 to 67% with PYL1 (Supplementary information, Figure S4). These results indicated that PYL13 can antagonize the activity of other PYLs in plants. PYL13 inhibition of other PYLs might result from direct interactions between PYL13 and other PYLs.

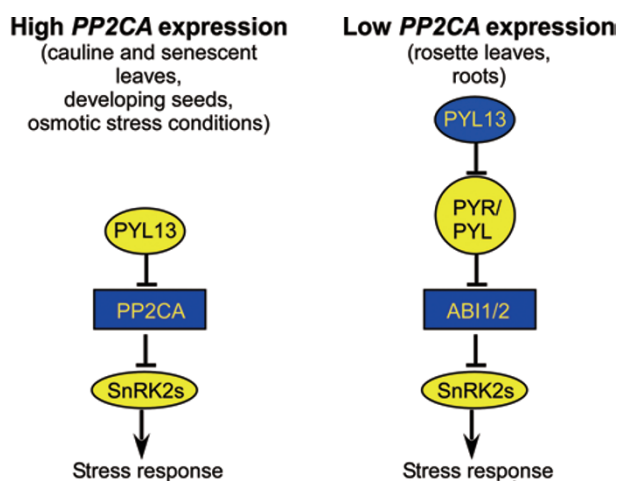

**Figure 5** PYL13 can antagonize the activities of other PYLs. **(A)** PYL13 interacts with other PYLs in yeast two-hybrid assays. PYL13 fused to the GAL4-activating domain (AD) was used as prey, and PYLs fused to the GAL4-DNA binding domain (BD) were used as baits. The interaction was determined by growth assay on media lacking His and His/Ade in the presence and absence of 10  $\mu$ M ABA. Dilutions ( $10^{-1}$ ,  $10^{-2}$ , and  $10^{-3}$ ) of saturated cultures were spotted onto the plates, which were photographed after 5 days. **(B)** PYL13 interacts with all PYLs in firefly luciferase (LUC) complementation assays in protoplasts. After transfection, protoplasts were incubated overnight under light at room temperature, and the LUC activities in living protoplasts were measured. Error bars indicate SEM ( $n = 6$ ). **(C)** Recombinant PYL13 binds to PYL1 and PYL2. His-tagged PYL13 (L13, ~22 kD) was used to pull down GST-tagged PYL1 (L1, ~51 kD) and PYL2 (L2, ~46 kD). **(D)** PYL13 can reduce the ability of PYL1 and PYL2 to inhibit ABI1 phosphatase activity. The phosphatase activity of ABI1 was measured (using pNPP) in absence or presence of 10  $\mu$ M ABA, with or without PYLs, and with PYL13-PYL dimers. The concentration of ABI1 and PYLs was 0.3  $\mu$ M. The  $A_{405}$  value of reaction without ABI1 was set as 0% and that of the reaction with ABI1 but without ABA and PYLs was set as 100%. Error bars indicate SEM ( $n = 6$ ). **(E)** PYL13 can reduce the abilities of other PYLs to inhibit the ABI1 activity in WT (Col-0) protoplasts. The ABA signaling pathway was reconstituted by co-expression of PYL13, PYLs, ABI1, SnRK2.6, and ABF2. The designation "2 $\times$  PYL13" indicates that the concentration of PYL13 plasmids was 2-fold greater than that of PYL2 plasmids. *ZmUBQ-GUS* was used as the internal control. After transfection, protoplasts were incubated for 4.5 h under light in the absence of ABA (open bars) or in the presence of 5  $\mu$ M ABA (closed bars). Error bars indicate SEM ( $n = 3$ ). **(F)** The PYL13 triple mutant Q38K/F71L/T135N cannot reduce the ability of PYL5 to inhibit the ABI1 activity in WT (Col-0) protoplasts. Error bars indicate SEM ( $n = 8$ ).

To test the functional significance of the three special residues (Q38, F71, and T135) in PYL13 on its inhibition of other PYLs, we co-expressed PYL13 triple mutant Q38K/F71L/T135N with PYL5, ABI1, SnRK2.6, and ABF2 in WT protoplasts. The triple mutation Q38K/F71L/T135N abolished the ability of PYL13 to antagonize the activity of PYL5 in protoplasts (Figure 5F). These results indicated that the three amino acid variations are responsible for the inhibition of other PYLs by PYL13.

## Discussion

In this study, we found that PYL13 has dual roles in *Arabidopsis* (Figure 6). First, PYL13 inhibits PP2CA, HAI2 and HAI3, which activates ABA responses. Second, PYL13 can negatively regulate ABA responses by antagonizing ABA-responsive activities of other PYLs. PYL13 interacts with all members of tested clade A PP2Cs and many of the other members of PYLs in an ABA-independent manner. The interaction between PYL13 and PYLs is weaker than that between PYL13 and PP2Cs. PYL13 has a particularly strong interaction with PP2CA and preferentially inhibits PP2CA activity. *PP2CA* is strongly expressed in cauline leaves and developing seeds, whereas it is only weakly expressed in rosette leaves and roots but the expression is upregulated by osmotic stress (<http://bar.utoronto.ca/efp/cgi-bin/efpWeb.cgi>). In conditions and tissues and developmental stages where *PP2CA* is prevalent, the primary function of PYL13 is likely to inhibit *PP2CA* to activate a subset of ABA responses. However, when *PP2CA* is not present at high levels, PYL13 would negatively regulate ABA responses by interacting with other PYLs. At present, it is unclear how PYL13 antagonizes other PYLs by interacting with them. It is possible that the interaction leads to interference with the ability of the other PYLs to bind ABA and/or to bind and inhibit downstream PP2Cs. This antagonistic role of PYL13 may be important in situations (e.g., very high ABA concentrations) where over-activation of ABA signaling needs to be prevented.

Yeast two-hybrid, pull-down, and co-IP assays demonstrated that PYL13 interacted with all clade A PP2Cs in an ABA-independent manner (Figure 3). Phosphatase activity assays showed that PYL13 strongly inhibited

**Figure 6** Model of the dual role of PYL13. PYL13 has dual roles in *Arabidopsis*. In tissues and conditions where *PP2CA* is highly expressed, PYL13 constitutively inhibits *PP2CA* activity (left panel). In tissues and conditions where *PP2CA* expression is low, PYL13 antagonizes other ABA-responsive PYLs via heterodimer formation (right panel).

PP2CA in an ABA-independent manner (Figure 4B). The inhibitory mechanism of PYL13 differs from the one reported previously for PYLs 5-10, which also interact with and inhibit PP2C activity in the absence of ABA [2, 27, 32]. Although these PYLs have high basal activities, ABA can enhance their interaction with PP2Cs and their inhibition of PP2C phosphatase activity [27, 38]. PYL10 also forms stable complexes with ABI1 in the absence of ABA, however, the binding of PYL10 to ABI1 is much stronger in the presence than in the absence of ABA [27]. In our study, in contrast, interactions between PYL13 and PP2Cs were unaffected by ABA, i.e., these interactions are completely ABA-independent (Figures 3 and 4A). The inhibition of PP2CA phosphatase activity by PYL13 with or without ABA is indistinguishable from that by PYR1/PYL2 with ABA (Figure 4B). These results are supported by the reconstitution of ABA signaling in protoplasts and by the phenotypes of the PYL13 overexpression transgenic plants (Figure 4A, 4C and 4D).

PYL13 can inhibit PP2CA activity *in vivo* (Figure 4C). When PYL13 was co-transfected with PP2CA, HAI2, or HAI3 in *abi1/hab1/abi2* protoplasts, the basal expression of *RD29B-LUC* in the absence of ABA was enhanced (Figure 4C). The PYL13 triple mutant Q38K/F71L/T135N lost the ABA-independent induction of the *RD29B-LUC* basal expression (Figure 4C), suggesting that it is these sequence variations that confer ABA-independent inhibition of PP2CA, HAI2, and HAI3. Moreover, the phenotype of PYL13 overexpression lines is similar to that of *pp2ca*-knockout mutants [34], whose seed germination is hypersensitive to ABA (Figure 4E). According to previous reports, the germination of *pp2ca-1* mutant was about 45% under 0.5  $\mu\text{M}$  ABA treatment and completely inhibited by 1  $\mu\text{M}$  ABA on day 5 after plating [34]. Our data showed that the germination of *OE-PYL13* #1 was 56% under 0.5  $\mu\text{M}$  ABA treatment and 14% under 1  $\mu\text{M}$  ABA treatment (Figure 4E). Consistently, the phenotype of *pyl13* mutants is in the same pattern as PP2CA overexpression lines [34], whose seedling establishment is hyposensitive to ABA (Figure 4F). However, the phenotype of *pyl13* mutants is very weak compared with *OE-PP2CA* transgenic lines, indicating that there are functional redundancy between PYL13 and other PYLs in their inhibition of PP2CA. This is supported by the ABA-independent inhibition of PP2CA by transiently expressed PYL8 and PYL10 in protoplasts (Supplementary information, Figure S6) and by the recombinant PYL8 and PYL10 in phosphatase activity assays reported by other groups [27, 6]. PYL8 and PYL10 inhibited approximately 30% and 50% of the phosphatase activity of PP2CA in the absence of ABA using a 10:1 ratio of PYLs:PP2CA [27]. Using a 4:1 ratio of

PYL8:PP2CA, a 10%-15% ABA-independent inhibition of PP2CA by PYL8 was reported [6]. These data demonstrated that PYL13 together with PYL8 and PYL10 regulate PP2CA activity, which may explain the weak ABA phenotype of *pyl13* single mutants. In *OE-PYL13* seedlings, PYL13 may act as a constitutive activator of ABA signaling to maintain a higher basal level of ABA signaling under unstressed conditions and to enhance stress responses under stressed conditions, which would be advantageous in dealing with the unpredictable environmental changes. Indeed, we observed that transcripts of *RD29A*, *KINI*, *COR15A*, and *RAB18* were more abundant in *OE-PYL13* seedlings than in the WT Col-0 under unstressed conditions and that the stress responses were enhanced in *OE-PYL13* seedlings under ABA treatments (Figure 2H and 2I). Thus, the improved drought resistance of *PYL13* overexpression plants (Figure 2) may be explained by PYL13 inhibition of the PP2Cs in leaf tissues including the guard cells. The fact that we did not observe any significant defect in drought resistance in *pyl13* mutant plants (data not shown) is consistent with the functional redundancy between PYL13 and other PYLs in regulating PP2CA.

In its second role, PYL13 antagonizes other ABA-responsive PYLs (Figure 6). PYL13 can interact with other PYLs independent of ABA in immunoprecipitation and mass spectrometric analyses (Supplementary information, Table S1), yeast two-hybrid assays (Figure 5A), LUC complementation (Figure 5B), and protein pull-down assays (Figure 5C). In the PYR/PYL/RCAR family, PYR1, PYL1 and PYL2 are homodimers, while PYLs 4-10 (except the untested PYL7) are monomers [27]. The monomeric mutant PYL2-I88K has a binding affinity with ABA about 7-fold higher than WT homodimeric PYL2 [27]. In the presence of ABA, dimeric PYLs need a conformational rearrangement to become monomers, which might be energy consuming. Heterodimer formation between PYL13 and other PYLs might reduce the binding affinity of other PYLs with ABA, thus antagonizing their activities. The heterodimer between PYL13 and other PYLs cannot be released by ABA, and this may interfere with the abilities of the other PYLs to bind to and inhibit PP2Cs. PYL13 can moderately reduce the activities of other PYLs in the presence of ABA as indicated by the analysis of ABI1 phosphatase activity (Figure 5D) and protoplast assays (Figure 5E). At later time points after ABA treatments, the stress-responsive genes maintain a similar expression level in *OE-PYL13* transgenic plants and in WT plants (Figure 2H). *PYL13* promoter::*GUS* reporter expression was detected in the roots, stems, leaves, flowers, imbibed seeds and guard cells (Supplementary information, Figure S7), indicating

that PYL13 is highly expressed in these tissues. Although the expression level of PYL13 in different tissues relative to the other PYLs is not known at this time, these results indicate that PYL13 may rein in or desensitize ABA responses by antagonizing the ABA receptors. By acting as a “constitutive activator” and a moderate antagonist of other PYLs, PYL13 may help to maintain ABA signaling within a reasonable range.

Overexpression of *CBF1* induces *COR* genes and confers freezing tolerance [40]. Overexpression of *DREB1A/CBF3* induces *DREB1*, *DREB2*, and *RD29A* genes and confers increased resistance to drought, high-salt, and freezing stresses [41]. Although *OE-OsMYB3R-2* exhibited enhanced cold tolerance in rice, it also resulted in growth retardation under normal conditions [42]. Similarly, *OE-DREB1A* in *Arabidopsis* caused severe growth retardation [41], and overexpression of *CBF1* in tomato resulted in a dwarf phenotype [43]. These results indicate that constitutive activation of stress-responsive genes increases stress tolerance but may also result in growth retardation. Thus, constitutive activation of stress-responsive genes may not be suitable for crop improvement. However, overexpression of *PYL13* did not result in any abnormal growth phenotype under normal conditions. Under normal conditions, expression of the stress-responsive genes was only slightly higher in *OE-PYL13* lines than in WT. Under stress conditions, however, these genes were induced more quickly in *OE-PYL13* lines than in WT.

PYL13 differs from other PYLs in the highly conserved ABA-binding pocket CLs 1-4. Q38 differs from K in CL1, F71 differs from L in CL2, and T135 differs from N in CL4 (Supplementary information, Figure S1). We mutated Q38K, F71L, and T135N on PYL13 to mimic other PYLs. None of these single mutants could mimic PYR1 or PYL2 with respect to the activation of *RD29B-LUC* expression in protoplasts. Double mutations of PYL13 (Q38K/F71L) and triple mutations (Q38K/F71L/T135N) could partially confer ABA-dependent induction of *RD29B-LUC* expression (Figure 1B). These three residues of PYL13 are not conserved even in other dicots (Supplementary information, Figure S5), indicating that PYL13 may have evolved after the other PYLs. The residues Q38 and F71 in CLs 1-2 are critical for the unique mode of action of PYL13 and are conserved in the genus *Arabidopsis* (Supplementary information, Figure S5). T135 in CL4 can enhance the effect of Q38K/F71L in inhibiting ABI1 in the presence of ABA. These results suggest that the variations in the three residues (Q38 in CL1, F71 in CL2, and T135 in CL4) can partially explain the functional difference between PYL13 and the other PYLs, which are ABA receptors. According to the PYR1

structure, K59 in PYR1 interacts with ABA’s carboxylic group [5], which is the corresponding position of Q38 in PYL13. This is consistent with our notion that Q38 is critical for ABA insensitivity of PYL13. In a screen for constitutively active receptors, PYR1 mutations located in 10 different residues were found to increase PYR1-HAB1 interactions in the absence of ABA [38]. One of these mutations in PYR1 (L87F) is located at the corresponding position of F71L in PYL13. This is consistent with our notion that F71 is critical for ABA-independent binding between PYL13 and PP2Cs. Triple mutations of PYL13 (Q38K/F71L/T135N) abolished the ability of PYL13 to antagonize the activity of PYL5 in protoplasts (Figure 5F), indicating that the three amino acid variations are also important for the antagonistic role of PYL13. We also noticed that one special residue (F71) is in the corresponding position (L111) of PYL3, which is one of the five most important residues for trans-homodimer formation of PYL3 [44]. These results indicated that the heterodimer between PYL13 and other PYLs should be different from other reported PYL homodimers or trans-homodimers, although mechanistic insight into the dimerization or multimerization requires structural evidence.

Our results suggest that PYL13 is not an ABA receptor but it can inhibit both the PYL receptors and the PP2C co-receptors. The novel functions of PYL13 make it an important modulator of ABA signaling. Because overexpression of PYL13 increases drought resistance, photosynthetic rate, and water-use efficiency in transgenic plants, this naturally evolved ABA receptor variant could be useful for increasing the drought resistance of crops.

## Materials and Methods

### Plant materials

*Arabidopsis thaliana* Col-0 was used as WT. The *pyl13-1* (SALK\_041176) and *pyl13-2* (SALK\_071488) mutants were obtained from ABRC harboring T-DNA insertions in the exon of At4g18620. The insertion was confirmed by the gene-specific primers *PYL13* CDSF and *PYL13* CDSR, and the T-DNA (pROK2) left border-specific primers LBb1.3 (ATTTTGCCGATTCG-GAAC).

The *PYL13* cDNA coding region was amplified by RT-PCR using the gene-specific primers *PYL13* CDSF and *PYL13* CDSR (Supplementary information, Table S2). The amplicon was cloned into the *EcoRI* and *Sall* sites of the binary vector pCAMBIA99-1 and confirmed by sequencing.

To generate the *ProPYL13:PYL13-HA-YFP* construct, the 2.79-kb *PYL13* promoter fragment amplified from Col-0 genomic DNA with the primers ProPYL13F and PYL13R (Supplementary information, Table S1) was cloned into the *Sall* and *BamHI* sites of the modified pSAT vector with YFP and 3HA tags at the C-terminus. The coding region of *PYL13* from pCAMBIA99-1-PYL13 was

then subcloned between the *PYL13* promoter and the *YFP* coding sequence. The whole insertion cassette was digested with *PI-Psp1* and re-inserted into pRCS2-htp binary plasmids [45].

The resultant plasmids were transformed into Col-0 as mediated by *Agrobacterium tumefaciens* GV3101. All transgenic plants were verified by PCR and northern blot assays. The T3 generation was used for further experiments.

### Plasmid construction

*ZmUBQ::GUS* was provided by J Sheen. *RD29B::LUC*, *ABF2-haemagglutinin (HA)*, *SnRK2.6-Flag*, and *His-PYLs* were the same as reported previously [19]. *ABF2* was replaced with *AB11*, *AB12*, *HAB1*, *HAB2*, *AHG1*, *PP2CA*, *HAI1*, *HAI2*, and *HAI3* using transfer PCR [46] with pHBT-PP2Cs primers (Supplementary information, Table S2). *PYR1* was replaced with *PYL13* using transfer PCR with pHBT-PYL13 primers (Supplementary information, Table S2). The pHBT-*His-PYL13* plasmid was used for mutagenesis with the QuikChange procedure (Stratagene) with specific primers (Supplementary information, Table S2). All plasmids were confirmed by sequencing.

*PP2CA*, *AB11*, *AB12*, *AHG1*, *PYL13*, and *PYL2* were cloned into the pGEX-6P-1 vector between *BamHI* and *EcoRI* sites using transfer PCR with pGEX-PP2Cs or pGEX-PYLs primers (Supplementary information, Table S2).

### Transient expression assay in Arabidopsis

Assays for transient expression in protoplasts were performed as described [4, 47]. Leaf strips (0.5 mm) were cut from the middle part of second leaves using a razor blade (VWR Scientific) and submerged in 15 ml of enzyme solution containing 20 mM MES, pH 5.7, 1.5% (w/v) cellulase R10 (Yakult Pharmaceutical Industry), 0.4% (w/v) macerozyme R10 (Yakult Pharmaceutical Industry), 0.4 M mannitol, 20 mM KCl, 10 mM CaCl<sub>2</sub>, 1 mM  $\beta$ -mercaptoethanol, and 0.1% BSA. The leaves were vacuum infiltrated for 30 min and then incubated without shaking for 3 h in the dark at room temperature. The enzyme/protoplast solution was diluted with 15 ml of W5 solution (2 mM MES, pH 5.7, 154 mM NaCl, 125 mM CaCl<sub>2</sub>, and 5 mM KCl) and filtered with a 75- $\mu$ m nylon mesh. Protoplasts were centrifuged at 100 $\times$  g for 2 min in a 30-ml round-bottomed tube (Sarstedt), resuspended in W5 solution, and rested for 30 min at room temperature.

Before transfection, protoplasts were changed into MMG solution (4 mM MES, pH 5.7, 0.4 M mannitol, and 15 mM MgCl<sub>2</sub>) to a final concentration of  $2 \times 10^5$  cells/ $\mu$ l. Protoplasts (100  $\mu$ l) were gently and thoroughly mixed with the plasmid DNA mixture (less than 10  $\mu$ l) and 110  $\mu$ l of PEG solution (40% w/v PEG-4000, 0.2 M mannitol, and 100 mM CaCl<sub>2</sub>), incubated for 5 min, washed with 440  $\mu$ l of W5 solution, and resuspended in 50  $\mu$ l of WI solution (4 mM MES, pH 5.7, 0.5 M mannitol, and 20 mM KCl). After transfection, protoplasts were incubated in WI solution without ABA or with 5  $\mu$ M ABA under light. The protoplasts were harvested after 4.5 h, frozen in liquid N<sub>2</sub>, and stored at -80 °C.

The frozen protoplasts were resuspended in 50  $\mu$ l of protoplast lysis buffer containing 2.5 mM Tris-phosphate, pH 7.8, 1 mM DTT, 2 mM DACTAA, 10% (v/v) glycerol, and 1% (v/v) Triton X-100. Protoplast lysates (20  $\mu$ l) were mixed with 100  $\mu$ l of LUC mix (Promega), and LUC luminescence was measured with a plate reader (Wallac VICTOR2 plate reader).

Protoplast lysates (2  $\mu$ l) were mixed with 10  $\mu$ l of 4-methylum-

belliferyl  $\beta$ -D-glucuronide (MUG; Gold Biotechnology) substrate mix (10 mM Tris-HCl, pH 8, 1 mM MUG, and 2 mM MgCl<sub>2</sub>). After the mixture was kept for 30 min at 37 °C, 100  $\mu$ l of 0.2 M Na<sub>2</sub>CO<sub>3</sub> was added, and GUS activity was measured using the plate reader with the excitation filter at 355 nm and the emission filter at 460 nm.

All the plasmids used in this assay were purified with the QIAGEN Plasmid Maxi Kit or the QIAGEN Plasmid Midi Kit. The quality of plasmid DNA is critical for high transfection efficiency. *RD29B::LUC* (7  $\mu$ g of plasmid per transfection) was used as the ABA-responsive reporter. *ZmUBQ::GUS* (2  $\mu$ g of plasmid per transfection) was used as the internal control. *ABF2-HA*, *SnRK2.6-Flag*, *PP2Cs-HA* (except *AB11*), and *His-PYLs* were used at 3  $\mu$ g per transfection. *AB11-HA* was used at 2  $\mu$ g per transfection. *His-PYL13* was used at 6  $\mu$ g per transfection when 2 $\times$  *PYL13* was needed.

### LUC complementation assay

cLUC and nLUC were PCR amplified from pCAMBIA-NLuc and pCAMBIA-CLuc and cloned into pHBT95 to form pHBT95-nLUC and pHBT95-cLUC using transfer PCR [46] with pHBT-nLUC and pHBT95-cLUC primers (Supplementary information, Table S2). *PYR1*, *PYLs* 1-11, and *PYL13* were amplified and cloned into pHBT-nLUC, and *PYL13* was cloned into pHBT-cLUC between *BamHI* and *SalI* using *PYL* primers (Supplementary information, Table S2). All plasmids were confirmed by sequencing.

All plasmids used in this assay were purified with the QIAGEN Plasmid Maxi Kit or the QIAGEN Plasmid Midi Kit. A 5- $\mu$ g quantity of purified plasmid was used per transfection. Protoplasts were incubated overnight in WI buffer containing 1% LUC mix (Promega). The LUC luminescence of live protoplasts was measured in 96-well plates with a plate reader (Wallac VICTOR2 plate reader).

### Drought-stress treatment

Seeds of the WT and *OE-PYL13* lines were collected from plants subjected to the same growth conditions and periods. The seeds were imbibed at 4 °C for 4 days in the dark and planted directly in soil. Plants were grown in a growth room at 22/18 °C under a 14-h light/10-h dark photoperiod with a light intensity of 100  $\mu$ moles photons m<sup>-2</sup> s<sup>-1</sup>. At 7 days after sowing (DAS), each pot was thinned to eight seedlings of uniform size. At 14 DAS, the drought-stress treatment was initiated by withholding water for 24 days, after which most WT plants had died. The plants were watered after 24 days of drought, and the surviving plants were counted 2 days later. The pots were rotated in the growth chamber every day to minimize the effect of environment. The complete experiment was repeated three times, each time with at least 3 replicates and at least 3 pots per replicate.

### Measurement of photosynthesis parameters and water loss

Plants used for photosynthesis and water-loss assays were grown under short-day conditions (10-h light/14-h dark). After 5 days of drought stress treatment as described in the previous section, photosynthesis parameters were measured. Maximal rates of stomatal conductance, transpiration, and photosynthesis were measured with an infrared gas analyzer (6400, Li-Cor, Lincoln,

NE, USA), and water-use efficiency was calculated. After photosynthetic measurements, leaf area was measured with a portable area meter (3000A, Li-Cor). The leaves were then dried for 48 h at 65 °C and weighed. For water-loss determination, whole rosettes of 18-day-old plants were cut from the base and weighed at the indicated time points.

### Protein purification and pull-down assay

*Escherichia coli* strain BL21 (DE3.0) was used to express the glutathione *S*-transferase (GST)-tagged recombinant proteins. Protein expression was induced by 1 mM isopropyl  $\beta$ -D-thiogalactoside for 12 h at 22 °C. GST-tagged proteins were purified from the soluble fraction using Glutathione Sepharose 4B (Amersham) under native conditions according to the manufacturer's instructions. The GST tag was removed by PreScission Protease at 4 °C overnight in PBS (137 mM NaCl, 10 mM phosphate, 2.7 mM KCl, and pH 7.3) with 1 mM DTT. His-tagged proteins were purified from the soluble fraction using PrepEase Histidine-tagged High Specificity Purification Resin under native conditions according to the manufacturer's protocol.

In the His-mediated pull-down assay, His-PYL13 and His-PYR1 (5  $\mu$ g) were immobilized on PrepEase Histidine-tagged High Specificity Purification Resin (USB) and incubated with PP2Cs (10  $\mu$ g) with or without 200  $\mu$ M ABA at room temperature for 20 min in 1 ml of binding buffer (PBS containing 0.1% (v/v) Triton X-100). The agarose was rinsed four times with 1 ml of binding buffer with or without 200  $\mu$ M ABA to remove unbound proteins, and the agarose was finally resuspended in 40  $\mu$ l of 1 $\times$  SDS loading buffer (50 mM Tris-HCl, pH 6.8, 2% SDS, 10% glycerol, 1%  $\beta$ -mercaptoethanol, 12.5 mM EDTA, 0.02% bromophenol blue) for 5 min at 100 °C. A 10- $\mu$ l volume of each suspension was resolved by SDS-PAGE and Coomassie blue staining.

### Co-IP experiments in protoplasts

PP2CA-HA, ABII-HA, and MYC-PYL13 plasmids (20  $\mu$ g each) were transiently expressed in WT Col-0 protoplasts. After transfection, protoplasts were incubated in WI buffer under light at room temperature for 16.5 h. Protoplasts were treated with 10  $\mu$ M ABA for 1.5 h before they were harvested, frozen in liquid N<sub>2</sub>, and stored at -80 °C. The frozen protoplasts were resuspended in 1 ml of immunoprecipitation (IP) buffer containing 50 mM Tris-HCl, pH 7.4, 150 mM NaCl, 1 mM EDTA, 0.1% (v/v) Triton X-100, and 1 $\times$  protease inhibitor cocktail (Sigma) with or without 10  $\mu$ M ABA and then centrifuged at 21 000 $\times$  g for 30 min at 4 °C. The supernatant was used as input and was incubated for 4 h at 4 °C with 30  $\mu$ l of monoclonal anti-HA-agarose antibody produced in mouse (Sigma, A2095). The agarose was washed four times using IP buffer with or without 10  $\mu$ M ABA and finally resuspended in 50  $\mu$ l of 1 $\times$  SDS loading buffer for 5 min at 100 °C. Protein samples (8  $\mu$ l each) were resolved by SDS-PAGE and were electrotransferred onto PVDF membranes (Millipore). Membranes were blocked in blocking buffer (PBS containing 0.1% Tween 20 (PBS-T) and 5% skim milk) for 2 h at room temperature and incubated in blocking buffer containing 1:500 diluted anti-HA (Sigma, SAB4300603) or 1:2 000 diluted anti-c-MYC (Abcam, ab9106) rabbit antibodies for 1 h at room temperature. After they were washed five times (5 min each) with PBS-T, membranes were incubated for 1 h in blocking buffer containing 1:5 000 diluted and stabilized goat anti-rabbit HRP-conjugated antibodies (Pierce, 32460). They were then

washed five times with PBS-T and proteins were detected using Lumi-Light Western Blotting Substrate (Roche).

### Phosphatase activity assay

Phosphatase activity was measured using the colorimetric substrate pNPP (Sigma). Reactions were performed in a reaction buffer containing 50 mM Tris-HCl, pH 7.5, 25 mM Mg(OAc)<sub>2</sub>, 2 mM MnCl<sub>2</sub>, 0.5 mM EGTA, 0.5%  $\beta$ -mercaptoethanol, and 0.5% BSA. ABA and PYLs were added as indicated. The concentration of PP2Cs and PYLs was 0.3  $\mu$ M. Reactions were initiated by the addition of pNPP to a final concentration of 50 mM. The hydrolysis of pNPP was measured by the absorbance at 405 nm ( $A_{405}$ ). Because His-PYL13 is difficult to purify, is prone to degradation, and rapidly loses activity, newly purified PYL13 was used for the phosphatase activity assay.

### Northern blot and real-time PCR

For northern blot analysis, total RNA was isolated with the QIAGEN-RNeasy Mini Kit (Qiagen, Valencia, CA, USA) according to the manufacturer's instructions. Four microliters of RNA was loaded onto agarose gels containing formaldehyde, and the gels were run at 72 volts for 4 h. After electrophoresis was completed, all RNA samples were transferred to Hybond-N<sup>+</sup> membrane by capillary transfer. Probes for the *PYL13* gene (for verification of *OE-PYL13* lines) and the *YFP* gene (for verification of *Pro-PYL13-YFP-3HA* transgenic lines) were labeled with the PCR-DIG probe synthesis kit (Roche, Nutley, NJ, USA) according to the manufacturer's instructions. The following primers were used for PCR reactions: *PYL13* forward: 5'-ATG GAA AGT TCT AAG CAA AAA C-3'; *PYL13* reverse: 5'-TTA CTT CAT CAT TTT CTT TGT GAG-3'; *YFP* forward: 5'-ACG TAA ACG GCC ACA AGT TCA-3'; *YFP* reverse: 5'-ACT GGT AGC TCA GGT AGT GGT TGT-3'. Pre-hybridization, hybridization, washes, and detection were performed using the DIG high primer DNA labeling and detection starter kit II (Roche, Nutley, NJ, USA) according to the manufacturer's instructions.

Ten-day-old *Arabidopsis* Col-0 and *OE-PYL13* seedlings were transferred to 1/2 MS liquid medium, pH 5.8, with 100  $\mu$ M ABA. The seedlings were kept in the light and harvested at the indicated time points. For real-time PCR assays, reactions were set up with iQ SYBR Green Supermix (BioRad, CA, USA). The CFX96 Touch™ Real-Time PCR Detection System was used to detect amplification levels and was programmed for an initial step at 95 °C for 2 min, followed by 40 cycles of 15 s at 95 °C and 1 min at 60 °C. Quantification was performed with three independent experiments. Relative expression levels of target genes and SD values were calculated using the 2<sup>- $\Delta\Delta$ CT</sup> method [48]. Primers used for real-time PCR are provided in Supplementary information, Table S3.

### Promoter GUS analysis

To generate *PYL13* promoter::GUS construct, the *PYL13* promoter (2 395 bp) and coding region were amplified from Col-0 genomic DNA with the following primers: GusF1 and GusR1, digested with *SalI* and *NcoI*; GusF2 and GusR2, digested with *NcoI* and *BamHI*, and cloned into the *SalI* and *BamHI* sites of the binary vector pBI101 and confirmed by sequencing. The resultant plasmid was transformed into Col-0 *Arabidopsis* mediated by *Agrobacterium tumefaciens* GV3101.

For histochemical detection of GUS activity, whole seedlings or coatless embryos were immersed in freshly prepared reaction buffer containing 100 mM sodium phosphate, pH 7.0, 10 mM sodium EDTA, 1% Triton X-100, 0.5 mM  $K_3Fe(CN)_6$ , 0.5 mM  $K_4Fe(CN)_6$  and 1 mM 5-bromo-4-chloro-3-indolyl- $\beta$ -D-glucuronic acid (X-gluc; Sigma) and vacuum infiltrated briefly, and then incubated overnight in the dark at 37 °C, and then washed with 70% ethanol several times until tissue is clear.

#### Immunoprecipitation and mass spectrometry

Proteins were extracted from *Pro-PYL13-YFP-3HA* transgenic lines and the Col WT with an extraction buffer containing 50 mM Tris-HCl, pH 7.5, 150 mM NaCl, 5 mM EDTA, 0.1% NP-40, 10% glycerol, 1 mM phenylmethylsulfonyl fluoride, 5 mM DTT, and one unit of Protease Inhibitor Cocktail (Sigma-Aldrich, CA, USA). Immunoprecipitation was performed with GFP polyclonal antibody (Invitrogen, CA, USA). The protein complex was eluted from Protein A agarose beads with urea elution buffer (8 M Urea, 20 mM Tris-HCl, pH 7.5, and 100 mM NaCl). After in-gel digestion, the protein complex was identified using Q-TOF LC/MS/MS. MS/MS spectra were processed and queried against the NCBI nr protein database using the MASCOT algorithm (<http://www.matrixscience.com>) for protein identification. Peptides were identified with a  $\Delta$  mass value (observed mass – theoretical mass) less than  $\pm 1.0$  D.

#### Sequence comparison

PYL13 homologs were obtained from The *Arabidopsis* Information Resource (TAIR, <http://www.arabidopsis.org>), DOE Joint Genome Institute (DOE JGI, <http://www.jgi.doe.gov/>), and Phytozome (<http://www.phytozome.org/>). Protein sequences were aligned using ClustalX 2.0.5 [49] with the default settings (Supplementary information, Data S1) and were viewed using GeneDoc software (<http://www.nrbsc.org/gfx/genedoc/>).

#### Accession numbers

Accession numbers of the proteins used in this study are provided in Supplementary information, Table S4.

#### Acknowledgments

This work was supported by US National Institutes of Health Grant R01GM059138 and by the Chinese Academy of Sciences.
