Sir,  
**Development of optic disc drusen in familial pseudopapilloedema: a paediatric case series**

Optic disc swelling in a child, with no other features suggestive of raised intracranial pressure is a challenging

clinical scenario. These children frequently undergo invasive investigations, such as neuroimaging and lumbar puncture, even though the clinical suspicion of serious pathology is low.

In this study, we report a new clinical presentation of benign optic disc swelling in five siblings of two families, where optic disc drusen were not present at first presentation, but developed many months later as shown on serial B-scan ultrasonography. We have termed this unusual presentation ‘familial pseudopapilloedema’.

Five children (two siblings from one family and three siblings from another family) underwent examination and B-scan ultrasonography at first presentation and at all subsequent examinations. Age range at first presentation was 18 months to 12 years with a mean of 6.5 years. The male to female ratio was 4:1. All five children had clinically apparent optic disc swelling without other ophthalmoscopic features of papilloedema (retinal nerve fibre layer swelling, surrounding disc haemorrhages, cotton wool spots, hyperemia, venous congestion, Patton’s lines, or exudates<sup>1</sup>). None had any symptoms suggestive of raised intracranial pressure, other neurological disease, or systemic upset (Table 1).

Serial B-scan ultrasonography showed no drusen at the first visit. However, all children developed small linear drusen at the optic disc over time (Figure 1). The mean time for development of drusen detectable on B-scan was 2.7 years. At no point was there optic nerve sheath dilation on B-scan. In two children, CT scans were conducted and reported as normal. A CT scan was avoided in three children because of the absence of optic nerve sheath swelling on sonography, the absence of symptoms of raised intracranial pressure and normal visual function.<sup>2,3</sup>

**Table 1** Summary table showing each of the five children’s age, reason for presentation, vision, refraction, and investigations

	A1	A2	A3	B1	B2
Age at presentation	18 months	4 years	6 years	12 years	7 years
Time taken for optic disc drusen to become visible on B-scan	12 months	18 months	4 years	3 years	4 years
Reason for referral to our unit	Family history of optic disc drusen	Optometrist referred for possible drop in visual acuity	Optometrist noted possible swollen optic discs on routine visit	Optometrist referred for ‘problems focusing’	Optometrist referred for possible swollen optic discs on routine visit
Refraction at last visit: right eye	+2.50 DS	+2.50 DS	+3.50/+0.50 × 90	−0.25 DS	+0.50/−0.25 × 180
Refraction at last visit: left eye	+2.25 DS	+2.50 DS	+3.50/+0.25 × 90	−0.50 DS	+0.50/−0.25 × 175
Vision at first presentation	6/7.5 BEO (Cardiff Cards)	R 6/7.5, L 6/7.5 (Snellen)	R 6/6, L 6/6 (Snellen)	R 6/6, L 6/5 (Snellen)	R 6/6, L 6/5 (Snellen)
Visual fields	No	No	Yes—Normal	Yes—Normal	Yes—Enlarged blind spot, otherwise normal
Lumbar puncture	No	No	Yes—Opening pressure 35 cm H <sub>2</sub> O	No	No
CT scan	No	No	Yes—Normal	Yes—Normal	No

A and B represent different families. 1, 2 and 3 represent different children within the families.

BEO denotes both eyes open.

Normal VF = No constriction to I4e, I2e, or V4e spot on the Goldmann Kinetic Perimeter.

**Figure 1** B-scan of small linear disc drusen (arrow) in one of the subjects.

**Discussion**

This is the first description of development of optic drusen in related children with pseudopapilloedema.<sup>4,5</sup> We found that reassuring symptomatology, the absence of optic nerve-sheath swelling on B-scans and a positive family history of pseudopapilloedema to be very helpful in excluding serious intracranial pathology, as well as reducing the need for lumbar punctures and CT scans.

Sir,  
**Eccrine syringofibroadenoma of the eyelid in association with eye prosthesis**

Eccrine syringofibroadenoma (ESFA) is a rare benign adnexal eccrine neoplasm. We report an ocular presentation with a unique location in the eyelid, associated with enucleation and long-standing prosthesis.

**Case report**

A 65-year-old man was referred to our eye clinic with a superomedial eyelid lesion just posterior to his lash line (Figure 1). The mass was present for 3 years and was slowly enlarging. He had undergone a left enucleation at the age of 1 year for a congenital abnormality of unknown aetiology and had a well-fitted prosthesis *in situ*.

The lesion was a 9 mm × 5 mm × 3 mm, solitary, elevated, non-tender polypoid mass on the under surface of the upper left eyelid posterior to the gray line. (Figure 1). His eye socket was unremarkable and there were no other cutaneous lesions. Microscopy of an excisional biopsy revealed downward proliferation of surface squamous epithelium, with thin strands of interconnecting epithelial cords and adjacent proliferation of conjunctival epithelium including goblet cells (Figures 2a and b). Epithelium surrounding a fibrovascular stroma was identified, and immunostaining with carcinoembryonic antigen showed

**Figure 1** Solitary, elevated, non-tender polypoid ESFA on the under surface of the upper left eyelid posterior to the gray line.
