

2. Residual heretozygosity exists within strain Hg/Hu, probably due to histocompatibility loci closely linked to the *a* or *hr* loci which were kept heterozygous during inbreeding.

Acknowledgments.—My thanks are due to Dr L. M. Boot, Dr K. P. Hummel and Dr G. D. Snell for supplying the strains of mice used in these tests.

EVOLUTIONARY GENETICS RESEARCH REPORTS

JOHN R. G. TURNER

Department of Biology, University of York, York YO1 5DD

Received 3.x.70

DATA gathered in studies of micro-evolution, relating to the genetic composition of natural populations at a particular time, differ from other biological data in that they are essentially unique and unrepeatable. But, except in a few journals, it is often difficult to publish such data, as it is bulky and irrelevant in itself to the understanding of a research paper. The danger is therefore real that such information will not survive the life of its discoverer. The loss to future scientists could be serious.

The new series *Evolutionary Genetics Research Reports* is designed to preserve data of this kind. Each report consists of tables of data on the population genetics of a particular organism, with a small amount of explanatory text.

The reports are deposited with the National Lending Library for Science and Technology at Boston Spa, Yorkshire, and copies may be had by application to them in the usual way.

Unless an author decides to have copies prepared for his own distribution, only a few of each report will be prepared. Lists of titles will be issued from time to time, but the normal method of access will be by a full citation of the report in the published paper which discusses the data. Reports are also listed in *British Research and Development Reports*, and the *NLL Announcement Bulletin* (from 1971). Five reports have so far been prepared, dealing with lepidoptera and snails.

Scientists wishing to preserve their data in this way should write for further details to the editor, at the address above.
