The polymeric mucin Muc5ac is required for allergic airway hyperreactivity

Schwartz¹ & Burton F. Dickey³

In asthma, airflow obstruction is thought to result primarily from inflammation-triggered airway smooth muscle (ASM) contraction. However, anti-inflammatory and smooth muscle-relaxing treatments are often temporary or ineffective. Overproduction of the mucin MUC5AC is an additional disease feature that, while strongly associated pathologically, is poorly understood functionally. Here we show that Muc5ac is a central effector of allergic inflammation that is required for airway hyperreactivity (AHR) to methacholine (MCh). In mice bred on two well-characterized strain backgrounds (C57BL/6 and BALB/c) and exposed to two separate allergic stimuli (ovalbumin and *Aspergillus* extract), genetic removal of *Muc5ac* abolishes AHR. Residual MCh responses are identical to unchallenged controls, and although inflammation remains intact, heterogeneous mucous occlusion decreases by 74%. Thus, whereas inflammatory effects on ASM alone are insufficient for AHR, Muc5ac-mediated plugging is an essential mechanism. Inhibiting MUC5AC may be effective for treating asthma and other lung diseases where it is also overproduced.

Asthma is a major health problem. Worldwide, it affects more than 300 million people. In the United States, it affects ~10 million and costs \$50–60 billion per year to treat. Asthma is characterized by airflow obstruction and structural changes associated with acute and chronic lung inflammation. Accordingly, the most widely used therapies are bronchodilators and anti-inflammatory agents¹. However, treatment results are often temporary or incomplete, and alternative strategies are lacking. We propose that this is due to an incomplete understanding of the mechanisms by which airflow obstruction and symptoms of dyspnoea, cough and wheezing are caused by the combined effects of inflammation, bronchoconstriction and additional non-contractile mechanisms. Non-contractile factors include airway wall thickening due to oedema and structural remodelling², loss of airway liquid surface tension due to plasma extravasation and fibrin accumulation³ and airway occlusion due to mucus hypersecretion⁴. With even just a small amount of airway smooth muscle (ASM) constriction, these non-contractile components can geometrically amplify airway resistance and increase the propensity for airways to close^{5–8}.

In human asthma and in animal models, mucin overproduction and hypersecretion are prominent pathological findings^{9–14}. In its most severe setting—fatal asthma—autopsy studies show that patients die from severe airflow obstruction caused by bronchoconstriction coupled with widespread mucous plugging^{15–17}. Even in mild to moderate asthma, where there is minimal baseline airflow limitation, patients respond to the inhaled cholinergic agonist methacholine (MCh) with exaggerated obstruction. Existing dogma labels this airway hyperreactivity (AHR) to MCh as resulting from excessive ASM contraction¹. Thus, unlike fatal asthma, where mucus hypersecretion is well recognized, in non-fatal exacerbations the potential obstructive role of mucus has been largely overlooked¹. In fact, in mild to moderate disease, mucin overproduction is highly prevalent¹², and the genomic region on chromosome 11p15 that encodes airway polymeric mucins is associated with AHR¹⁸. Furthermore, mucin overproduction and changes in its biochemical/biophysical properties correlate with asthma exacerbations^{4,19,20}. These associations in humans are supported in animal models where mucin overproduction and AHR to MCh are both induced, and where in addition to causing ASM contraction, MCh is also known to cause mucin secretion^{21,22}. Thus, the obstructive effects of ASM contraction may be amplified by acute thickening of mucus on airway surfaces. While these associations are strong, establishing the causative significance of mucus secretion in asthma has been hampered by a lack of experimental evidence and the absence of effective clinical interventions that target the chief glycoprotein components of airway mucus, the secreted polymeric mucins MUC5AC and MUC5B.

MUC5B predominates in healthy human lungs, and its levels in asthma remain stable or in some cases decrease^{10,12,23}. On the other hand, MUC5AC levels in asthma increase significantly and consistently^{4,10,12,13}. Mice display similar tightly controlled expression patterns: High baseline *Muc5b* gene expression remains stable following antigen challenge while low baseline *Muc5ac* gene expression increases markedly²⁴. Furthermore, whereas *Muc5b* is required for airway homeostasis and anti-bacterial defence, *Muc5ac* is not essential for these functions²⁵, and in lung injury *Muc5ac* is actually detrimental²⁶. These findings implicate *Muc5ac* as a deleterious and dispensable glycoprotein component of airway mucus. Thus, it is suitable to investigate as a potential target for reducing obstruction in asthma.

In allergic asthma, a biphasic response occurs after allergen inhalation. Acutely, IgE crosslinking induces mast cell and basophil histamine release, causing a brief episode of airflow

obstruction (what is most commonly thought of as an ‘asthma attack’). The acute early-phase response lasts a few minutes to a few hours, and it is followed by a late-phase response that lasts for several hours to several days. Clinically, the late phase is considered to be the main driver of disease progression²⁷. Accordingly, even after baseline lung function is restored following an acute asthma episode, the ensuing late phase displays sustained pathophysiology hallmarked by AHR to inhaled agonists such as MCh, inflammation characterized by recruitment of eosinophils and interleukin (IL)-13-producing type-2 T helper cells, and airway remodelling linked to induced MUC5AC production²⁸.

MUC5AC/Muc5ac induction is a well-characterized epithelial response to allergic (type 2) inflammation. IL-13 has been implicated in the pathogenesis of human asthma²⁹ and in animal models^{30,31}. However, compared with its reported effects on leukocytes³² or ASM³³, the relative importance of IL-13 signalling in epithelia³⁴ and the mechanisms by which it elicits asthma-like pathophysiology are unclear. *MUC5AC/Muc5ac* gene expression is induced by IL-13 through direct stimulation of airway epithelial cells^{24,30,31,34–36}. In mice, *Muc5ac* expression is central to the allergic mucous phenotype. It is induced maximally 48–72 h after antigen challenge²⁴, times that are concordant with late-phase human asthma. We thus hypothesized that eliminating this type-2 inflammation effector would protect against asthma-like disease in mice.

Here we show the functional significance of *Muc5ac* in allergic AHR, inflammation and mucus obstruction. In *Muc5ac*^{−/−} mice³⁷, we demonstrate that even in the presence of ongoing inflammation, significantly reduced heterogeneous mucous plugging abolishes AHR.

Results

***Muc5ac* is a major polymeric mucin in allergic mouse lungs.** In wild-type (WT) mice, immunohistochemical analyses demonstrated constitutive *Muc5b* production that was similar in healthy and ovalbumin (OVA)-sensitized and -challenged airways (Fig. 1a,b). OVA challenge induced *Muc5ac* protein and alcian blue-periodic acid Schiff's positive glycoconjugate production (Fig. 1a,b), which were marked by a ~400-fold increase in *Muc5ac* transcripts (Fig. 1c). In OVA-challenged *Muc5ac*^{−/−} mice, *Muc5ac* transcripts were absent (Fig. 1c), and bronchial epithelial mucin content was significantly reduced (Fig. 1d,e). We thus examined the development of allergic asthma-like phenotypes in *Muc5ac*^{−/−} mice.

***Muc5ac* is required for AHR to MCh in allergic mouse lungs.**

To determine the consequences of disrupting *Muc5ac* expression on airflow obstruction, we assessed lung mechanical function and AHR to MCh. OVA challenge did not alter baseline lung resistance (Supplementary Fig. 1a), demonstrating that inflammatory and mucous metaplastic changes did not disrupt steady-state airflow measurably in this model of late-phase asthma. However, when exposed to MCh, OVA-challenged WT and heterozygous mice both demonstrated significant AHR. By contrast, *Muc5ac*^{−/−} mice were protected (Fig. 2a; Supplementary Fig. 1b). To confirm these findings, we also assessed AHR in C57BL/6 and BALB/c WT and congenic *Muc5ac*^{−/−} mice exposed to aerosolized *Aspergillus oryzae* extract (AOE). AOE is a fungal allergen pertinent to human asthma that upon mucosal sensitization elicits strong asthma-like responses in mice³⁸. In WT animals, AOE challenge caused AHR to MCh, but in both *Muc5ac*^{−/−} lines, AHR was abolished (Fig. 2b,c; Supplementary Fig. 1b). Importantly, protection occurred irrespective of C57BL/6 and BALB/c strain-specific airway- and tissue-localized

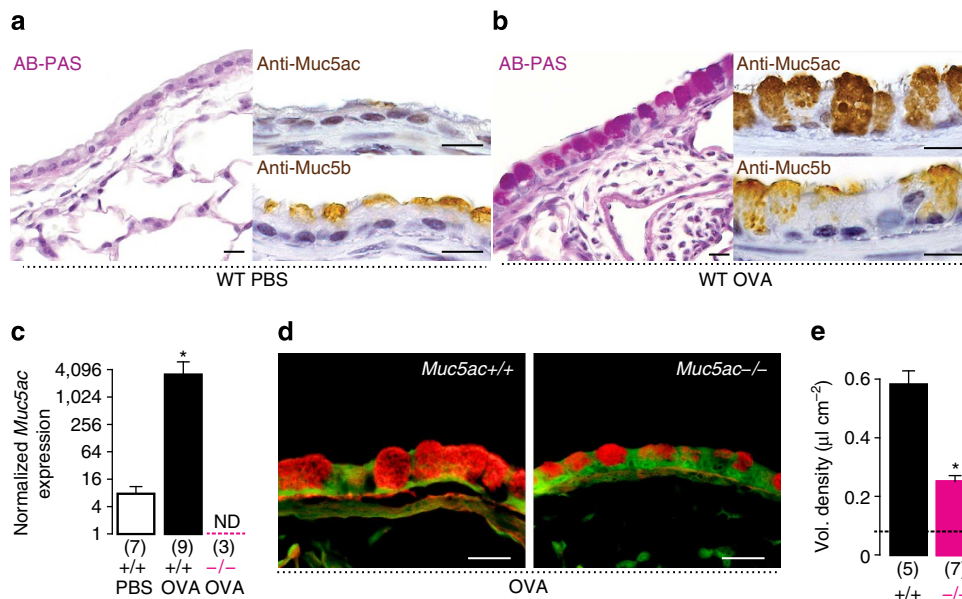

Figure 1 | Mucous metaplasia is significantly reduced in *Muc5ac*^{-/-} airways. (a and b) Mucin production in saline- (a) and OVA- (b) challenged WT mice. AB-PAS, anti-Muc5ac and anti-Muc5b staining shows upregulated Muc5ac and sustained Muc5b in allergic airways. (c–e) *Muc5ac* messenger RNA increased 383-fold in OVA-challenged WT mice (+/+), but it was undetectable in *Muc5ac* knockout (-/-) mice (c), resulting in a 67% reduction in mucous metaplasia detected by periodic acid fluorescent Schiff's staining (d and e). Scale bars, 20 μm (a,b,d). Mean, s.e.m. (c and e). **P* < 0.05 (one-tailed) by a unpaired *t*-test (c and e), with Welch's correction for unequal variances in c. ND, not detected. Numbers in parentheses, 'N' mice. 'Vol.', volume. Dashed line in e, baseline in saline-challenged WT mice.

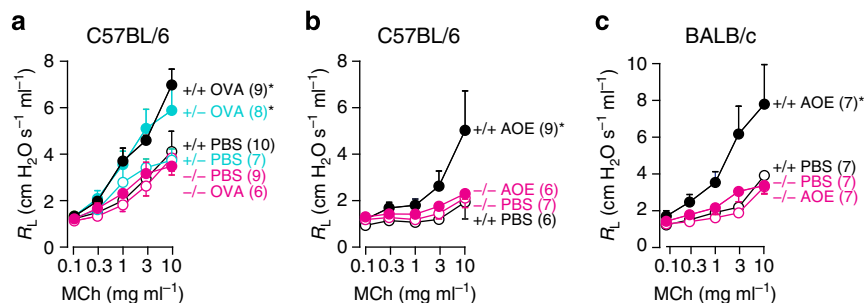

Figure 2 | *Muc5ac* is required for AHR to MCh. Lung resistance (R_L) responses to MCh in WT (+/+), *Muc5ac*^{+/-} (turquoise) and *Muc5ac*^{-/-} (magenta) mice after saline (open circles), OVA (closed circles in a) or *Aspergillus oryzae* extract (AOE; closed circles in b and c). Mean, s.e.m. (a–c). **P* < 0.05 between slopes of best-fit regression lines by one-way ANOVA. Numbers in parentheses, 'N' mice.

pathophysiologies. To partition AHR on airway and tissue scales, we assessed lung mechanics by measuring input impedance. As reported previously³⁹, AHR was strongly influenced by tissue resistance and elastance in C57BL/6 mice (Fig. 3a; Supplementary Fig. 2) and by tissue and central airway resistance in BALB/c mice (Fig. 3b; Supplementary Fig. 2); *Muc5ac* deficiency was protective irrespective of the background strain. Thus, in diverse models of allergic asthma, *Muc5ac* was required for AHR to MCh.

Mucin secretion alone is not sufficient to cause AHR. Because acute mucin secretion was required for AHR to MCh with no residual effect attributable to ASM hypercontractility (Figs 2 and 3), we next determined whether mucin secretion was sufficient to acutely induce AHR independently of bronchoconstriction. In airway epithelial cells, P2Y₂ purinergic receptor stimulation is a major pathway for mucin secretion⁴⁰. P2Y₂ receptors are activated by the endogenous agonists ATP and uridine triphosphate trisodium salt (UTP)^{40,41}. ATP is rapidly

dephosphorylated to adenosine, a signalling molecule that itself induces bronchoconstriction; ATP was thus inappropriate for these studies. Since UTP and its metabolites do not cause acute ASM contraction⁴², we challenged WT C57BL/6 mice with OVA or saline, and 72 h later we mechanically ventilated them and measured immediate changes in secretion and lung resistance in response to UTP. In OVA-challenged WT mice, although UTP rapidly stimulated secretion (Fig. 4a,b), there was no disruption of airflow (Fig. 4c). Thus, although *Muc5ac* was critical for allergic AHR in the presence of ASM-mediated bronchoconstriction following MCh, UTP-induced mucin secretion alone did not evoke an AHR response.

Allergic inflammation fails to drive AHR in *Muc5ac* null mice. Type-2 inflammation is critical for AHR in allergic mouse models^{30,31}. Given the essential role for *Muc5ac* in AHR identified here (Figs 2 and 3), and the requirement for *Muc5b* in inflammatory cell clearance²⁵, we determined whether *Muc5ac* expression mediated AHR by modulating allergic inflammation.

Figure 3 | Muc5ac mediates mouse strain-specific allergic airway pathophysiology. Conducting airway resistance (ΔR_{AW}), tissue resistance (ΔG_{T1}) and tissue elastance (ΔH_{T1}) were measured using oscillatory mechanics to assess input impedance. **(a)** In WT C57BL/6 mice, *Aspergillus oryzae* extract (AOE)-induced AHR (closed black circles) was dominated by changes in peripheral tissue mechanics (ΔG_{T1} and ΔH_{T1}) compared with changes in R_{AW} . **(b)** In WT BALB/c mice, AOE-induced AHR (closed black circles) had central airway (ΔR_{AW}) and tissue dominance (ΔG_{T1}), whereas ΔH_{T1} was not significantly different following AOE (NS) in WT mice. In both congenic strains, responses were significantly blunted in *Muc5ac*^{-/-} mice (closed magenta circles). Mean, s.e.m. * $P < 0.05$ between slopes of best-fit regression lines by one-way ANOVA. 'NS', not significant. Numbers in parentheses, 'N' mice.

Compared with saline-challenged mice, there were significant increases in leukocyte numbers that varied with environmental exposure (OVA versus AOE) and genetic diversity (C57BL/6 versus BALB/c) (Supplementary Table 1). In WT C57BL/6 mice, there was an 8.5-fold difference in eosinophilic responses to OVA and AOE; between WT BALB/c and C57BL/6 strains, there was a 9.7-fold difference in eosinophil numbers in response to AOE (Fig. 5). However, between WT and *Muc5ac*^{-/-} mice in each of these groups, eosinophilic inflammation was not significantly different (Fig. 5; Supplementary Fig. 3; Supplementary Table 1). Thus, full protection from AHR in the absence of *Muc5ac* occurred although asthma-like allergic inflammation was sustained.

Reduced heterogeneous airway closure in *Muc5ac* null mice.

Since AHR was abolished in *Muc5ac*^{-/-} mice although inflammation remained intact, we hypothesized that AHR was mediated by physical obstruction of the airway lumen by *Muc5ac*. Obstruction could result from uniformly thickened mucus causing an increase in resistance to airflow via homogeneous changes in mean airway lumen diameter. Alternatively, obstruction could result from non-uniform mucous aggregates causing an increase in resistance to airflow via heterogeneous occlusion and airway closure (Fig. 6a). To compare these, AOE-challenged WT and *Muc5ac*^{-/-} mice were mechanically ventilated and treated with increasing doses of MCh as shown in Fig. 2. During peak changes in resistance following 10 mg ml⁻¹ MCh, lungs were fixed transmurally with methacarn to preserve airway geometry and enable quantification of secreted mucus *in situ*⁴³.

We generated a model of homogenous obstruction by fitting changes in resistance and airway lumen diameter to Poiseuille's law. In AOE-challenged *Muc5ac*^{-/-} mice, resistance (R) to airflow decreased 2.3-fold (Fig. 6b). Assuming laminar flow, Poiseuille's law predicts a 23% increase in mean lumen diameter uniformly (Fig. 6c, magenta dashed line). However, our histological measurements showed that mean lumen diameters improved by 39% and 32% in bronchi and bronchioles, respectively (Fig. 6d). If applied to the model above, airflow resistances would be three- to fourfold improved (Fig. 6c, black lines), but they were not. Thus, a model in which the prevention of AHR in *Muc5ac*^{-/-} mice was the result of protection from uniform mucus thickening and homogenous airflow obstruction is incongruent with our observations. Indeed, the poor fit of the findings above, the anatomically diverse responses observed in our AHR studies (Fig. 3a,b) and previous data from murine and computational models^{2,8} more strongly support heterogeneous obstruction as the major determinant of AHR.

To determine whether *Muc5ac*-mediated heterogeneous obstruction contributes to AHR, we analysed the distributions of individual airway lumen sizes relative to their anatomical locations. We observed non-uniform distributions of lumen sizes. In *Muc5ac*^{-/-} lungs, there was a rightward shift in the distribution of airway lumen sizes compared with WT (Fig. 6e,f), which was consistent with protection from AHR. Furthermore, in WT mice, we also observed markedly greater proportions of bronchiolar airways with diameters of $\leq 100 \mu\text{m}$ (Fig. 6f), a measurement consistent with a previously calculated threshold for airway closure⁸. Because components such as the epithelial and ASM layers and secreted mucus can all influence

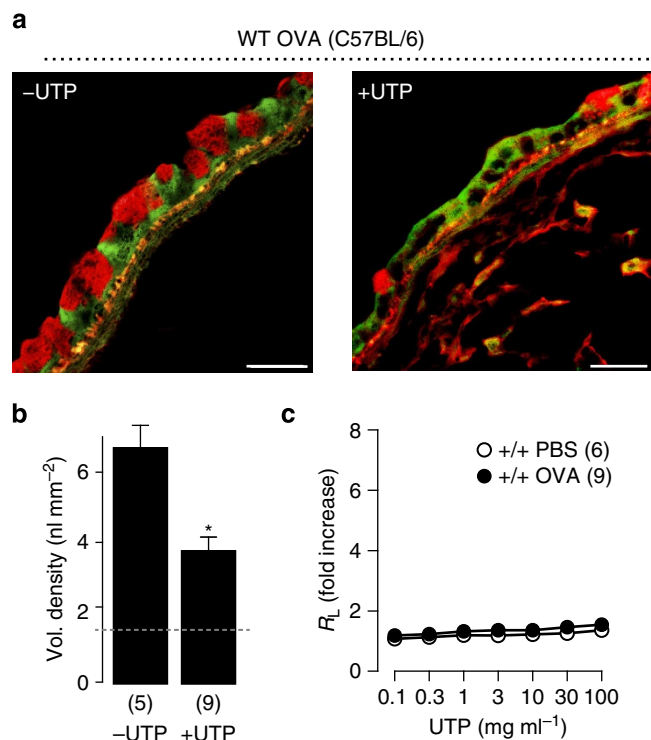

Figure 4 | Acute mucin secretion does not cause AHR. WT mice were OVA or PBS challenged, and then anaesthetized, ventilated and exposed to UTP (0.1–100 mg ml⁻¹) or vehicle (saline). **(a)** In OVA-challenged lungs fixed immediately after dose-response tests, there was an acute decrease in periodic acid fluorescent Schiff's (PAFS) staining in UTP (right panel) compared with vehicle (–UTP, left panel) treated mice, demonstrating acute UTP-induced secretion. Scale bars, 20 μ m. **(b)** Quantitation of UTP-induced changes in PAFS staining in OVA-challenged mice. **(c)** No effect of UTP on R_L in either PBS- or OVA-challenged WT mice. Mean, s.e.m. in **b** and **c**. Numbers in parentheses, 'N' mice. 'Vol.', volume. Dashed line in **b**, baseline in saline-challenged WT mice. * $P < 0.05$ by the t -test.

airway closure, we next determined how these were affected in *Muc5ac*^{-/-} mice.

In our functional studies, epithelial mucin production/secretion and ASM contraction were both required for AHR as shown in Figs 2–4. We thus compared the specific contributions of secreted mucin, epithelial thickening and ASM to anatomically localized changes in airway sizes. In bronchi, overall airway diameter (including ASM, epithelium, mucus and lumen) was $539 \pm 78 \mu$ m in WT mice and $683 \pm 31 \mu$ m in *Muc5ac*^{-/-} mice ($P = 0.051$, one-tailed t -test), and in the bronchioles, these values were $274 \pm 15 \mu$ m and $310 \pm 22 \mu$ m, respectively ($P = 0.096$, one-tailed t -test). Although not statistically significant as a combined group, these data suggested that secreted *Muc5ac* in the airway lumen could have some effect(s) on the behaviour of underlying tissues. We therefore derived a measure of composite airway wall/mucus thickness by subtracting airway lumen diameters (Fig. 6d) from overall airway diameters. In the bronchi, this was not significantly different between WT and *Muc5ac*^{-/-} mice (103 ± 21 versus $76 \pm 9 \mu$ m, respectively; $P = 0.124$, one-tailed t -test). By contrast, in the bronchioles, differences in composite airway wall/mucus thickness were significant ($71 \pm 14 \mu$ m in WT versus $44 \pm 10 \mu$ m in *Muc5ac*^{-/-}; $P = 0.006$, one-tailed t -test). Mucus contribution to composite airway wall/mucus thickness was reduced in *Muc5ac*^{-/-} mice compared with WT as expected, since a major mucin component was missing (Fig. 6g). However, there were also significant differences in

Figure 5 | *Muc5ac* deficiency does not reduce allergic inflammation. WT (black) and *Muc5ac*^{-/-} (magenta) mice had similar numbers of eosinophils in lung lavage fluid irrespective of OVA or *Aspergillus oryzae* extract (AOE) antigen challenge or strain background variables. For all groups, saline-challenged mice had $< 10^4$ eosinophils in lung lavage fluid (see Supplementary Table 1). Mean, s.e.m. $N = 6$ –11 mice per group.

epithelial tissue and ASM components (Fig. 6h,i). Epithelial hypertrophy is directly related to mucin production⁹, so its contribution was also predictable (Fig. 6h). By contrast, the effect of *Muc5ac* deficiency on the contribution of ASM, which was significantly lower in *Muc5ac*^{-/-} bronchi and bronchioles, was surprising (Fig. 6i).

Collectively, these findings reinforce the concept AHR is caused by contractile and non-contractile factors that contribute interdependently. Since AHR in allergic mouse lungs was dependent on a combination of ASM contraction and *Muc5ac* secretion (Figs 2–4), and since changes in airway structure and function did not fit models of homogenous changes in airflow, these findings further support the hypothesis that epithelial *Muc5ac* secretion during MCh-induced ASM constriction causes the formation of mucous plugs that potentiate heterogeneous airflow disruption.

***Muc5ac* mediates heterogeneous mucous occlusion in mice.** In WT airways, mucous plugs were present and *Muc5ac* was abundant (Fig. 7a); in *Muc5ac*^{-/-} airways, plugs were infrequent and mucus was sparse (Fig. 7b). Throughout the lungs, mean lumen mucin volume density, a homogeneous measure of mucous content across airway surfaces, was reduced by 32% (Table 1). Thus, as with lumen diameter, assuming uniform mucus accumulation across all airway surfaces and fitting these to Poiseuille's law results in changes in resistance that exceed those observed experimentally.

We thus determined the extent and distribution of mucous occlusion percentage, a sensitive measure of the fractional volume of airspaces occupied by mucus. This was used previously to quantify the prevalent but heterogeneous airway plugging observed in fatal asthma, which showed that $> 98\%$ of airways in these patients were occluded with mucus by 20% or more¹⁵. In *Muc5ac*^{-/-} airways, overall mean lumen occlusion percentage was reduced by $\sim 60\%$ (Table 1; Fig. 7c). Similar to human asthma¹⁵, plugging was also heterogeneous in mice (Fig. 7d). In WT airways, median occlusion was 6.7% compared with 0% in *Muc5ac*^{-/-} airways. Furthermore, in WT mice only 12% of airways were occlusion

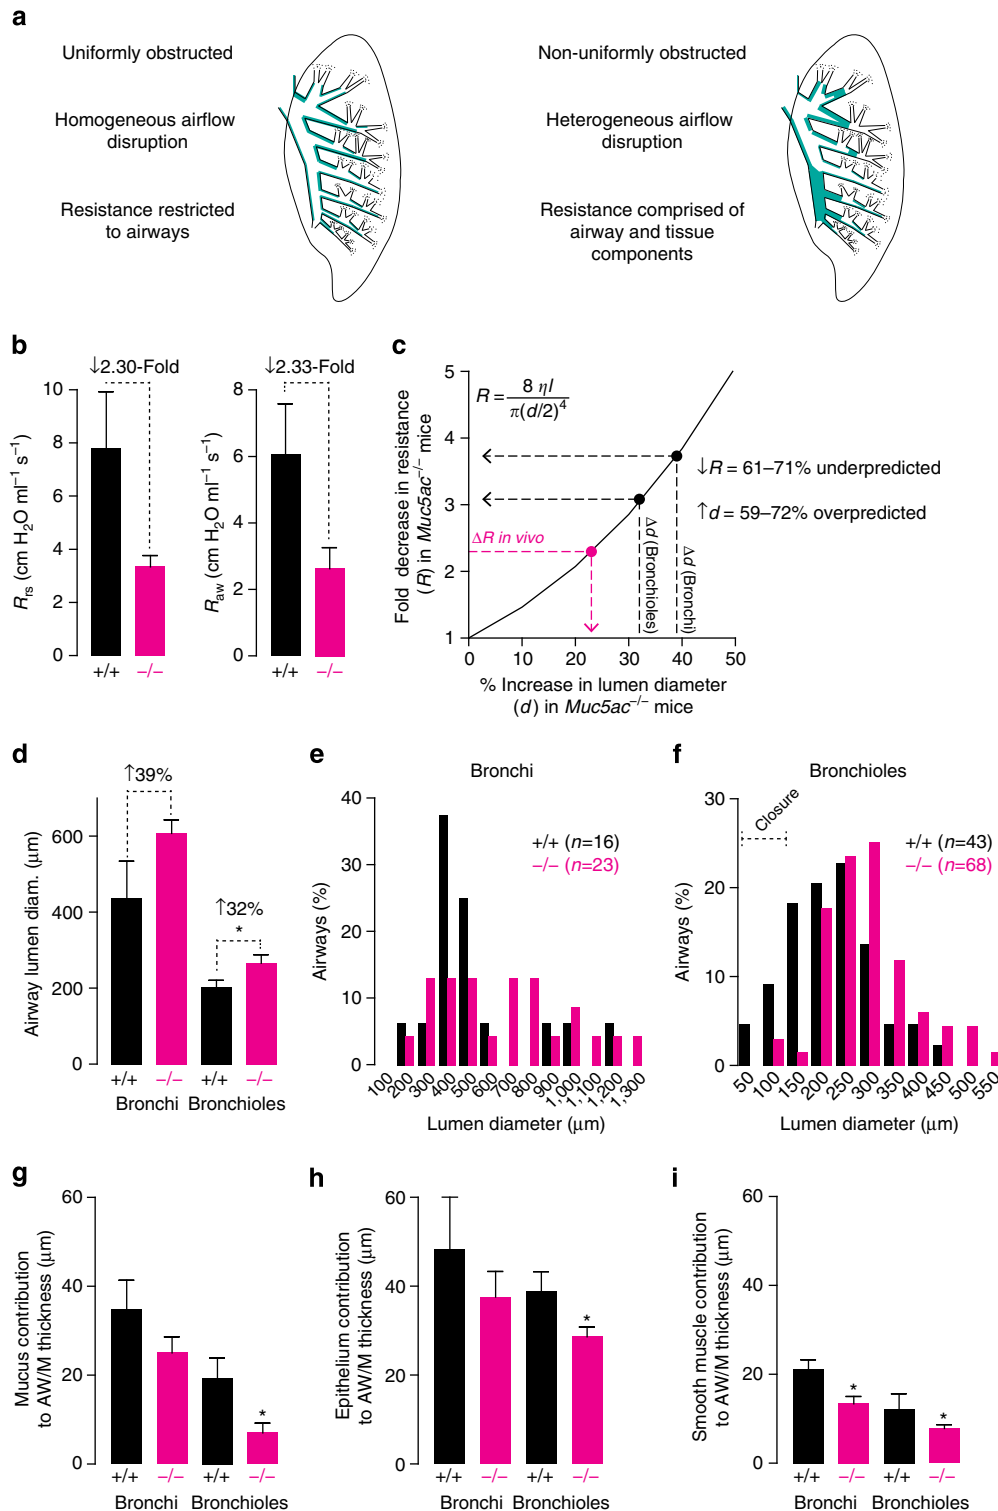

Figure 6 | *Muc5ac* deficiency protects against heterogeneous airflow obstruction. (a) Models of the effects of uniform versus non-uniform obstruction on airflow. (b and c) Changes in peak total lung and airway resistances (ΔR) following 10 mg ml⁻¹ MCh in WT and *Muc5ac*^{-/-} mice ($n = 7$ per genotype) (b) were fit to Poiseuille's law (equation in c) to predict changes in airway lumen diameter (magenta point and dashed arrow). Viscosity (η) and length (l) were held constant. (d–f) Mean (d) and distributions (e,f) of airway lumen diameters measured in methacarn-fixed lungs; changes in mean lumen diameter were also fit to the equation in c (black points and dashed arrow). (g–i) Contributions of mucus, airway epithelium and smooth muscle to changes in composite airway wall/mucus (AW/M) thickness. Mean, s.e.m. in b,d and g–i. x axis labels bin maximum values in e and f. $N = 4$ WT and 5 *Muc5ac*^{-/-} mice. * $P < 0.05$ by a t -test.

free, and 32% were occluded by $\geq 20\%$. In *Muc5ac*^{-/-} mice, 51% of airways were occlusion free, and only 8.2% were occluded by $\geq 20\%$.

To further dissect the sources of heterogeneous obstruction, we determined the distribution of occlusions by airway generation. In WT mice, occlusions of $\geq 20\%$ were common in axial bronchi

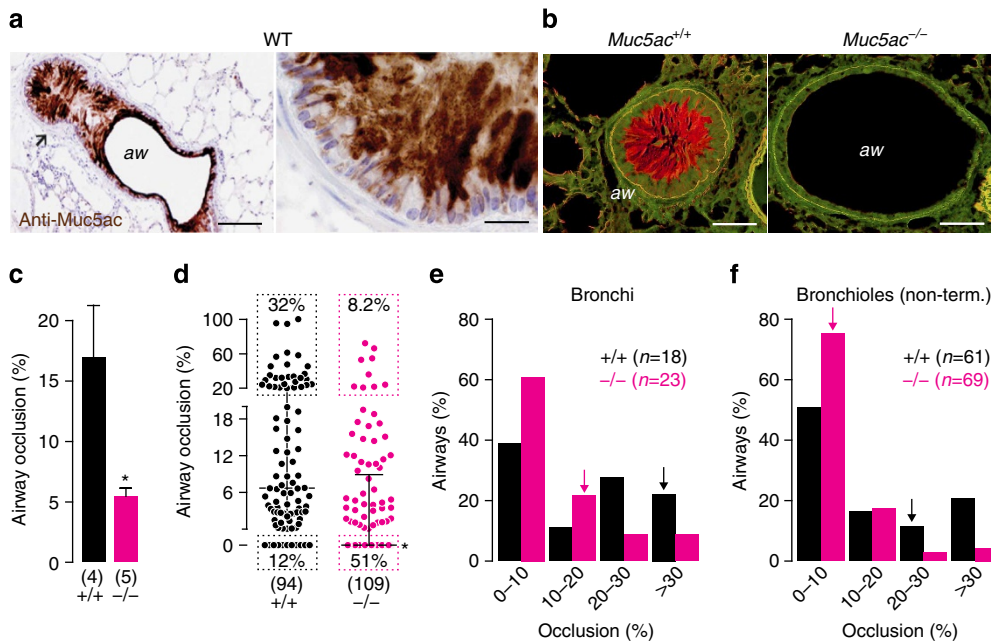

Figure 7 | Muc5ac deficiency reduces mucous plugging. (a and b) Inhaled MCh caused mucous plugging in WT allergic mouse airways (aw). | Table 1 Measurements of secreted mucus in mice during bronchoconstriction. | | | |
|---|-------------|------------------------------|----------------|
| Histological measurement | WT | <i>Muc5ac</i> ^{-/-} | <i>P</i> value |
| <i>V</i> _{mucus} per surface area (mm ³ cm ⁻²) | | | |
| All airways | 0.71 ± 0.08 | 0.48 ± 0.43 | 0.313 |
| Axial bronchi | 1.16 ± 0.09 | 0.84 ± 0.11* | 0.032* |
| Non-terminal bronchioles | 0.58 ± 0.13 | 0.30 ± 0.06* | 0.041* |
| <i>V</i> _{mucus} per anatomic region (mm ³ mm ⁻³) | | | |
| All airways | 3.9 ± 1.1 | 2.3 ± 0.6 | 0.185 |
| Axial bronchi | 0.8 ± 0.1 | 0.6 ± 0.2 | 0.122 |
| Non-terminal bronchioles | 3.1 ± 1.0 | 1.7 ± 0.5* | 0.099 |
| % Occlusion per anatomic region | | | |
| All airways | 18 ± 4.3 | 7.2 ± 1.4 | 0.020* |
| Axial bronchi | 20.1 ± 5.7 | 11.7 ± 2.6 | 0.097 |
| Non-terminal bronchioles | 16.8 ± 1.3 | 6.3 ± 1.2 | 0.022* |

WT, wild type.
Values are means ± s.e.m. **P*<0.05 by a unpaired *t*-test. *N* = 4 WT and 5 *Muc5ac*^{-/-} mice.

(50% of airways) and bronchioles (31% of non-terminal airways) (Fig. 7e,f). In *Muc5ac*^{-/-} mice, occlusions of ≥20% were present in only 17.4% of axial bronchi (2.7-fold reduction) and 7.2% of bronchioles (4.6-fold reduction). Thus, disruption of the *Muc5ac* gene in mice resulted in protection from a heterogeneous airway plugging phenotype that was similar to the pathology observed in fatal human asthma¹⁵.

Discussion

AHR in asthma is currently thought to result primarily from inflammation-triggered ASM hypercontractility¹. However, there is growing evidence that in addition to ASM-driven narrowing,

obstruction is also mediated by significant non-contractile factors^{2,4,8,44}. Here we report that in allergically inflamed mouse lungs, Muc5ac is an essential non-contractile mediator of AHR. These findings have important implications with respect to mechanisms of asthma pathophysiology. They could also inform the development of more effective treatments that target MUC5AC. These could especially benefit patients in whom bronchodilators or corticosteroids are ineffective^{1,45}.

In our studies, mucin secretion and ASM contraction were both required for AHR. Although there were C57BL/6 and BALB/c strain-specific differences between central airway and peripheral tissue responses, there was no residual AHR to MCh in *Muc5ac*^{-/-} mice at whole-lung or partitioned airway and tissue scales. Thus, our data challenge the notion that AHR in allergic asthma is dominated by exaggerated ASM contraction. That dogma is grounded on studies showing ASM hypertrophy in pathological tissues, hypercontractility of excised ASM from asthma patients and on protection provided by bronchodilating β-agonist treatments¹. Such findings show association and suggest necessity for ASM hypercontractility in AHR, but they do not prove its sufficiency. Our studies also showed that inducing mucin secretion without bronchoconstriction did not evoke AHR. Thus, in mice, while ASM contraction and mucin secretion are both necessary for acute AHR, neither alone is sufficient. Rather, ASM contraction and mucin secretion mediate AHR cooperatively. These findings highlight the need to better understand coordinated contractile and non-contractile mechanisms of airflow obstruction in asthma².

In addition to finding that ASM contraction and Muc5ac secretion were both required for AHR, we also found an apparent interdependence between mucus secretion and ASM-mediated airway constriction. Airway diameters and ASM thickness were both significantly reduced in allergic *Muc5ac*^{-/-} lungs after MCh (Fig. 6). This may reflect effects of mucus secretion on airway surface tension and the propensity for airway closure, or it

may demonstrate the ability of airways with less mucus to remain open following deep lung inflation manoeuvres that are administered between MCh doses in our experimental set-up. In asthma patients, these could affect the ability of deep breaths to maintain open airways. Alternatively, during dose-response tests in our studies, enhanced passage of aerosolized MCh through open airways in *Muc5ac*^{-/-} mice could have increased its deposition in the terminal bronchioles, which have little to no smooth muscle or mucin expression and thus contribute minimally to AHR. Lastly, changes in ASM constriction could have been related to changes in ASM hypertrophy in allergic *Muc5ac*^{-/-} mice. However, this is unlikely since the total amount of ASM was not different between allergic WT and *Muc5ac*^{-/-} mice (Supplementary Table 2). Nonetheless, further investigation is needed to determine the potential significance and mechanisms of these intriguing interactions between ASM and non-contractile components.

To this end, other non-contractile factors of AHR have been studied^{2,3,8}. Plasma extravasation and fibrin accumulation can reduce airway liquid surface tension and cause acute airway closure³. Studies in animal and computational models present this alternative to ASM dominance as heterogeneous closure occurring via 'sudden liquid bridge formation'^{2,8}. Our findings are consistent with this conceptual framework, which we advance by defining *Muc5ac* as a key molecular mediator. Indeed, it is plausible that aqueous-soluble factors become enriched within hydrated and heterogeneously distributed *Muc5ac*-containing mucous aggregates. Alternatively, each could occur independently yet synergize to mediate airway closure during bronchoconstriction.

Our studies also demonstrated that *Muc5ac* mediates AHR independently of the degrees of allergic inflammation. Differences in genetic and stimulus-dependent allergic inflammation were striking (Fig. 5; Supplementary Fig. 3; Supplementary Table 1). However, although inflammation is critical for allergic AHR^{30,31}, and secreted mucins can modulate immune function and resolve inflammation^{25,26,46}, eosinophils in OVA- and AOE-challenged *Muc5ac*^{-/-} lungs did not differ from WT (Fig. 5). By contrast, mucous plugs throughout *Muc5ac*^{-/-} airways were significantly reduced in abundance and severity (Fig. 7). Thus, protection from AHR was mediated not by altered inflammation but through reduced plug formation: in constricting airways, acute physical obstruction caused by *Muc5ac* was essential for AHR. This segregation between *Muc5ac* function and preserved type-2 inflammation is consistent with *in vivo* findings in nematode-infected mice. 'Allergic' type-2 inflammation stems from off-target anti-helminth responses. In nematode-infected *Muc5ac*^{-/-} mice, although intestinal type-2 inflammation is sustained, animals do not effectively control infections in the absence of *Muc5ac*³⁷. Rather than affecting inflammation, the type-2 inflammation effector *Muc5ac* (but not the homeostatic intestinal mucin *Muc2*) directly impairs worm viability³⁷. It remains to be determined whether the mechanisms by which *Muc5ac* selectively inhibits worm growth also promote mucus aggregation and plugging in the airways.

Indeed, biochemical/biophysical mechanisms by which secreted mucus occludes airways in asthma are poorly understood. Our current understanding of mucins in asthma is largely limited to anecdotal evidence of altered physical properties¹⁹, to associations drawn from pathological studies showing increased goblet cell numbers and mucin contents in biopsies from a wide range of disease severities^{4,47} and to pervasive airway plugging in autopsy specimens obtained from fatal cases^{15–17}. Some studies do show that patients have persistently abnormal mucus and mucociliary clearance^{4,11,19,20,23,48,49}. However, the obstructive consequences of mucin secretion in AHR and non-fatal

exacerbations have remained unclear. This may be due in part to a lack of appreciation of interrelated ASM contractile and epithelial secretory processes. MCh induces both ASM contraction and epithelial mucin secretion^{21,22}. In the airways, mucins become hydrated⁵⁰, swelling to produce a thick gel that amplifies the obstructive effects of narrowing initiated by ASM^{2,4}. Applying strategies that combine relaxing ASM with reducing mucin production and secretion and/or enhancing mucociliary clearance could improve disease treatment.

While potentially beneficial, clearance-enhancing mucolytics and expectorants have been disregarded as asthma treatments. At achievable doses, existing therapies such as hypertonic saline and *N*-acetylcysteine show poor efficacy and tolerability, because the high concentrations that are needed to clear mucous plugs are irritating and cause bronchoconstriction^{4,51–53}. For example, although *N*-acetylcysteine is the only Food and Drug Administration-approved reducing agent available as an inhaled adjunct mucolytic, clinical data do not support its use⁵⁴, reflecting its low mucolytic activity at high mucin concentrations^{55,56} and at a neutral airway pH (7.14 in mice⁵⁷). We speculate that improved inhaled mucolytic agents can reduce plugging and AHR in asthma. However, it will be critical for any strategy that reverses or prevents obstruction, to do so safely while also protecting mucous-mediated defence.

Muc5ac is one of two polymeric mucins that are the predominant glycoproteins in airway mucus. The other, *Muc5b*, is expressed abundantly at baseline and remains present following allergic inflammation in mice (Fig. 1a,b). *Muc5b* is critical for homeostatic defence. *Muc5b*^{-/-}, but not *Muc5ac*^{-/-}, mice have severely impaired mucociliary clearance functions, resulting in accumulated particles and bacteria in the airways, and ultimately in death due to uncontrolled infection²⁵. In humans with asthma, as *MUC5AC* expression increases, *MUC5B* expression either remains stable or decreases markedly^{10,12}, with divergent *MUC5AC:MUC5B* expression ratios associated with worse AHR¹⁰. Thus, targeting *MUC5AC*, while preserving or enhancing *MUC5B*, should be considered for any improved mucolytic therapies.

Two possible means for controlling the effects of *MUC5AC* on AHR are through targeting gene expression mechanisms or the glycoprotein itself. Critical expression signals include IL-13 and epidermal growth factor receptor ligands^{34–36}. A monoclonal anti-IL-13 antibody has shown promise in early human trials²⁹, and a small-molecule inhibitor of MAPK13 was effective in allergic mice⁵⁸. However, a recent trial of epidermal growth factor receptor blockade in chronic obstructive pulmonary disease (COPD) failed, because at doses that achieved minimal changes in mucin production, adverse effects occurred⁵⁹. Transcriptional control of *MUC5AC/Muc5ac* gene expression through regulators including SPDEF (SAM pointed domain-containing Ets transcription factor), Notch and hypoxia-inducible factor-1 (refs 24,60–62) have also been identified, but they are not currently targetable.

As an alternative to controlling gene expression, more selective results could potentially be yielded by disrupting the secreted *MUC5AC* polymer or by blocking its assembly. Recent studies have revealed mechanisms for controlling mucin disulfide bond-mediated polymerization⁶³ and patterns of selective mucin glycosylation^{23,49}. These may provide better targets for preventing mucus aggregation and airway plugging acutely. Specifically, by determining which glycan or oligomerization mechanisms are specific for *MUC5AC* versus *MUC5B*, novel strategies could be designed to reduce AHR by selectively inhibiting *MUC5AC*-mediated plugging while maintaining *MUC5B*-mediated airway defence. Future studies are directed at investigating these possible mechanisms. Since excessive

MUC5AC is also a common problem in airway diseases such as COPD and cystic fibrosis, whose inflammation and MUC5AC gene induction pathways differ significantly from allergic asthma, targeting the physical glycoprotein and polymeric properties of MUC5AC could have broader therapeutic applications.

Methods

Experimental animals. Studies were performed with approval of the animal care and use committees of the University of Colorado (approval number 97412(01)E) and the MD Anderson Cancer Center (approval numbers 05-04-046, 05-05-04334 and 00001214-RN00). *Muc5ac*^{-/-} mice were generated previously³⁷. Mice were backcrossed onto congenic C57BL/6 and BALB/c lines using marker-assisted analysis at the MD Anderson Research Animal Support Facility-Smithville, Animal Genetics Services lab. After achieving 100% carriage of 77 C57BL/6 and 82 BALB/c strain-specific markers, lines were backcrossed 3–5 additional generations. Mice were either bred as homozygous nulls or heterozygotes. C57BL/6 and BALB/c mice from the Jackson Labs (Bar Harbor, ME) were used for congenic backcrossing and as WT controls. Male and female mice were used starting at 7–8 weeks age. Before and after exposures, mice were housed under specific pathogen-free conditions in ventilated cages (≤ 5 mice per cage) with a 12-h light/dark cycle and with food and water available *ad libitum*. Mice were placed into experimental and control groups chronologically.

Ovalbumin- and *A. oryzae* induced lung inflammation. For studies in OVA-challenged mice, animals were sensitized intraperitoneally (i.p.) with 4 weekly injections of 20 μ g OVA, 2.25 mg alum in saline (Sigma, St Louis, MO). Seven days after the last injections, sensitized mice were then exposed to 5 ml of a 2.5% (w/v) OVA aerosol delivered until the full volume was administered⁹. For AOE challenge, mice were exposed by the nose-only inhalational challenge. AOE is a commercially available fungal protease/peptidase complex produced by submerged fermentation of *A. oryzae* (catalogue no. P6110 Sigma). Although marketed as a 'protease,' our own microscopic analysis shows that it is a crude extract rich in fungal particles, although no live organisms were detected when samples were cultured. In addition, endotoxin levels were <50 units ml⁻¹ (Endosafe-PTS, Charles River Laboratories, Wilmington, MA). AOE was used previously to elicit allergic inflammation in mice following bolus intranasal application³⁸. For aerosol exposures here, a 5-ml volume of a 10% v/v solution of AOE was made in PBS containing 2.5% w/v OVA (Sigma) and 1% v/v antifoam A (Sigma). Aerosols were generated using an Ultravent jet nebulizer, which when driven at 30 psi, generates particles with a mean mass aerodynamic diameter of $<1 \mu$ m⁶⁴. In mice, $>80\%$ of the particles generated are respirable and deposit in the lower airways efficiently⁶⁴. Exposures were made in custom-built nose-only chambers and lasted until a 5-ml volume was delivered (40–45 min). Mice were AOE challenged once weekly for 4 weeks. Allergic inflammation was confirmed by lung lavage and Giemsa staining. *Muc5ac* messenger RNA levels were determined by quantitative PCR as described previously²⁴.

Airway hyperreactivity. Lung function was measured 72 h post OVA challenge or 48 h post AOE challenge using a flexiVent (Scireq, Montreal, Quebec, Canada). Mice were anaesthetized with 2.0 g kg⁻¹ urethane (i.p.). This was sufficient to provide up to 4 h of sedation, although experiments lasted only 20–40 min. Mice were tracheostomized with a blunt beveled 18 G Luer stub adapter. Once ventilated (150 breaths per min, 10 ml kg⁻¹, against 3 cm H₂O positive end expiratory pressure), mice were paralysed by continuous infusion of succinylcholine chloride (10 μ g g⁻¹ min⁻¹, i.p.). Baseline total lung resistance (R_L) using a single-compartment model and the input impedance parameters, Newtonian (airway) resistance (R_{AW}), tissue resistance (G_{TI}) and tissue elastance (H_{TI}) were determined. Changes in R_L , R_{AW} , G_{TI} and H_{TI} in response to successive, increasing doses of MCh chloride (Sigma, Cat no. A2251; 0.1–10 mg ml⁻¹) or UTP (Sigma, Cat no. 94370; 0.1–100 mg ml⁻¹) administered by an in-line ultrasonic nebulizer were assessed. Heart rates were monitored by electrocardiogram. At 10 mg ml⁻¹ MCh, heart rates often fell below 200 beats per min and did not recover. At this point, no further dose-response measurements were made.

Mucin production and secretion. To assess mucin production, mouse lungs were fixed by intratracheal formalin administration and stained using periodic acid fluorescent Schiff's (PAFS) to assess and quantify intracellular glycoconjugates^{9,65}. To assess secretion, WT C57BL/6 mice were OVA challenged, ventilated on a flexiVent and exposed to inhaled UTP to induce secretion (0.1–100 mg ml⁻¹) or inhaled saline to control for ventilator- or vehicle-induced secretion (seven doses repeated over the same intervals used for UTP). After UTP or saline exposures, lungs were immediately fixed intratracheally with formalin. Acute mucin secretion in airway tissues was assessed by measuring changes retained in PAFS-positive contents. Secretion was defined as decreased staining due to acute depletion of intracellular stores in UTP versus saline-treated animals.

Mucous plugging and airway measurements. Tissues were fixed by adapting a method previously used to preserve colonic mucus using methanol-based Carnoy's fixative (methacarn)⁴³. Methacarn is a highly permeant non-crosslinking preservative that rapidly penetrates tissues transmurally while minimizing mucus disruption and tissue shrinkage⁴³. Animals were carried through full dose-response curves. During peak increases in R_L following 10 mg ml⁻¹ MCh, mice were rapidly euthanized by anaesthetic overdose and cessation of mechanical ventilation. Mice remained connected to the ventilator, which by default stopped at end expiration (3 cm H₂O positive end expiratory pressure). Skin covering the lower sternum was removed, and 400 μ l of methacarn was injected into the pleural space. The trachea was ligated immediately below the tracheal cannula. These steps took less than 15 s, thus minimizing changes in airway constriction and mucus transport. Lungs were fixed *in situ* for 30–60 min, then removed and immersion fixed with the trachea still ligated for 24–48 h in methacarn at 4 °C. Tissues were transferred to 100% methanol (changed twice over a 48-h period). While remaining fully immersed in methanol, left lungs were sectioned into uniform 1.92-mm-thick filets and imaged to calculate volume by Cavalieri estimation (319 ± 31 and 322 ± 24 mm³ for WT and *Muc5ac*^{-/-} mice, respectively). Tissues were then paraffin processed and sectioned (5 μ m thickness).

Histological assessments were made using alcian blue-periodic acid Schiff's (AB-PAS) and periodic acid fluorescent Schiff's (PAFS) to assess total mucin, Muc5ac (clone 45M1, 1:100 dilution), and MUC5B (custom polyclonal antisera, 1:2,000) production^{37,65,66}. Intracellular mucin content levels and the extent of mucous plugging were examined by systematic uniform random sampling⁶⁷. Stained slides were scanned by two blinded investigators using an Olympus BX63 microscope and cellSens software (Olympus USA, Center Valley, PA). At least five axial bronchi per mouse were analysed. For non-axial 'bronchiolar' airways, samples were analysed by selection of every fifth $\times 20$ image in a continuous x-/y-map of all lung samples per slide. Mucin and airway area were calculated using point-grid counting. Basement membrane length and airway circumferences were measured in cellSens. Data were calculated as volume densities (volume per unit surface area of basement membrane)^{9,65} and as extracellular mucous volume fractions relative to lung and airway volumes (multiplied by 100 to express as % occlusion)⁶⁷.

Statistical analyses. All statistical analyses were performed using GraphPad Prism 5.04 with a *P* value cutoff of 0.05 considered significant. Inflammation, mucin production and mucin secretion data were compared between groups using unpaired one-way Student's *t*-tests, with corrections made for unequal variances (Welch's), or non-Gaussian distribution (Mann-Whitney) where appropriate. For multiple comparisons, analysis of variance (ANOVA) with a Dunnett *post hoc* correction or Kruskal-Wallis test for non-Gaussian distribution was used. For dose-response tests, curves were compared using ANOVA for repeated measures, and using ANOVA with a Dunnett *post hoc* correction to compare slopes after linear regression against log-transformed MCh doses. Both analyses of dose-response tests provided congruent results. Sample sizes were chosen based on the numbers of WT saline versus allergic mice required to achieve a statistically significant difference.

Foster of the Duke University Medical Center were helpful in the design of our aerosol system. This work was supported by the National Institutes of Health Grants R01HL080396 and R21ES023384 (C.M.E.); R21HL120770 (D.A.S.); UH2HL123442 (C.M.E. and D.A.S.); R01HL097000 (B.F.D.); R01HL070952 (M.R.B.); R01DK097075, R01HL092188, R01HL098294 and R01HL119837 (H.K.E.); P01HL114457 (M.R.B. and H.K.E.); R01HL109517 (W.J.J.); and grants by the American Heart Association 14GRNT19990040 (C.M.E.) and the Crohn's and Colitis Foundation of America (H.K.E.). T.A.W. was supported by the intramural research program at the National Institute of Allergy and Infectious Diseases/National Institutes of Health. Additional support was provided by National Institutes of Health Cancer Center Support Grants P30CA016672 (M.D.).

Anderson Cancer Center, including the Research Animal Support Facility-Smithville, Animal Genetics Services) and P30CA046934 (University of Colorado).

Author contributions

D.S.R., F.T., D.R.L., A.A.F., D.N.H., M.A.McG., M.M.McE., O.W.W., E.S. and M.G.R. bred animals, performed exposures, performed studies of lung function, inflammation and mucin production/secretion. K.N.K., T.A.W., H.K.E., M.R.B., M.J.T., D.A.S. and B.F.D. assisted in study design and data analysis. C.M.E. conceptualized the study, performed experiments and wrote the manuscript.
