Abstract

Formation and differentiation of salt crystal is a most common as well as challenging problem during protein crystallography. Although there are some methods used for their differentiation but non of them are totally reliable and also require a good crystal (final stage crystal). To escape this problem the screening was done as everyone do. But during optimization the additives/salts were ignored at first and optimization screen was made just based on different buffers and precipitant. After selecting suitable buffer, the type and percentage of precipitant was optimized. We got some ugly crystals and with the help of effective previous screening additives/salts were chosen and concentration were optimized. At optimization of methods, protein crystallization ratio and physical conditions were done to get good crystals better in size and shape. This approach is able to escape the risk of salt crystal formation which can reduce our wastage of time and money.

Introduction

As the crystallization behavior of a target protein is not usually known beforehand, investigators use screens.

Salt crystals can also form owing to combination of the precipitants, buffers and additives present in screens together with the components of the protein solution (3).

There is no reliable way to distinguished protein and salt crystals except by putting the crystal in the X-ray beam (1,2,3,4).

This process can be time-consuming if the crystals are small and require an optimization step to enlarge them sufficiently for X-ray diffraction.

This is a quite challenging problem in protein crystallography therefore an approach able to escape the problem is desirable.

The approach has been developed and also a protein crystal fallows it.

Goal

To develop an approach in this direction

Why interesting

This approach is able to escape the risk of salt crystal formation which can reduce our wastage of time and money.

Approach

Totally based on carefully maintenance and analysis of screening results.

Optimization should be stepwise i.e. first of all buffers and precipitants after that salts / additives should be optimize.

At last concentration and ratio of protein, methods and physical conditions should be optimize.

Methodology

Different screens.

Plant latex

Screening

Optimization

Each components (varied in

concentration) of solutions of

good screening conditions

prepared manually.

Optimizations

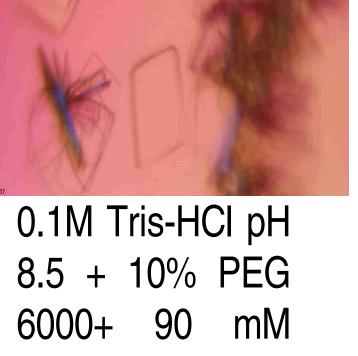

0.1M Tris-HCl, pH 8.5 + 10% PEG 6000

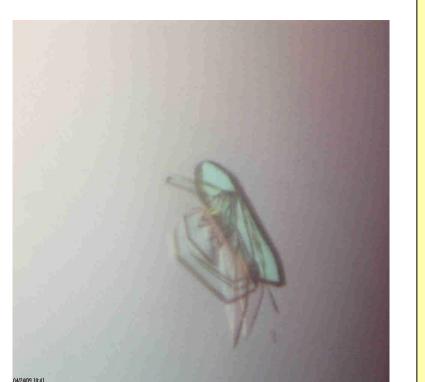

0.1M Tris-HCl, pH 8.5 + 10% PEG 90mM 6000 NaBr

NaBr,protein:crys tallization solution ratio 3:1 by siting drop method

0.1M Tris-HCl pH 8.5 + 6% PEG6000+ 90 NaBr,protein:cryst allization solution 2:3 ratio hanging drop method

Crystals were tested in-house for x-ray diffraction and diffract up to 2.9Å

Conclusions

An approach has been developed to minimize the risk of salt crystal formation during protein crystallization. The approach has been also successfully proved with the help of a novel protein.
