Outline of the talk

- Introduction
- Learning Machines: A Bottom-up Approach with a Network
- Analysis of Networks
- From Networks to Personalized Medicine

Precedings : doi:10.1038/npre.2012.7118.1 : Posted 3 Apr

Introduction

Molecular Networks

- Protein-protein Interaction Networks
- Metabolic Networks
- Regulatory Networks - TF-gene Networks
- Post-translational Networks - Kinase-substrate Networks
- RNA Networks - TF-miRNA Networks, miRNA-gene Networks

Phenotypic Networks

- Co-expression Networks
- Genetic Networks

What is a Disease Network?

Disease Genes (A Snapshot from 2007)

Less than 10% of human genes are known to have association with specific diseases [Barabási, 2011].

Of these ~19% are known to be oncogenes (November 16, 2011; Cancer Genome Project).

Learning Machines: A Bottom-up Approach with a Network

- Co-expression
- Differential Expression
- Differential Co-expression
- Co-expression Dynamics

Definition

pairwise similarity pattern (spatial or temporal) of expression vectors.

Different statistical measures [Bandyopadhyay, 2011].

Definition

varying patterns (spatial or temporal) of expression vectors in different phenotypes.

SAM, t-test, etc.

Definition

Pairwise varying dependence (spatial or temporal) between expression factors in different phenotypes.

On/off case and gap/substitution case [Dettling, 2005].

Definition

Pairwise varying dependence (spatial or temporal) between expression vectors based on another expression vector.

[Li, 2002].

Making Networks Robust by Integration

Supervised Approach

$$LS = \ln \frac{P(L|E)/\sim P(L|E)}{P(L)/\sim P(L)}$$

$P(L|E)$ and $\sim P(L|E)$ are the observed linkage frequencies of annotated genes operating in the same and in different pathways, respectively, whereas $P(L)$ and $\sim P(L)$ are the prior annotations [Lee, 2004].

Unsupervised Approach

$$V_c(i, j) = \sqrt[\alpha]{\sum_{k=1}^n \xi_k(i, j) W_k(i, j)^\alpha}$$

Analysis of Networks

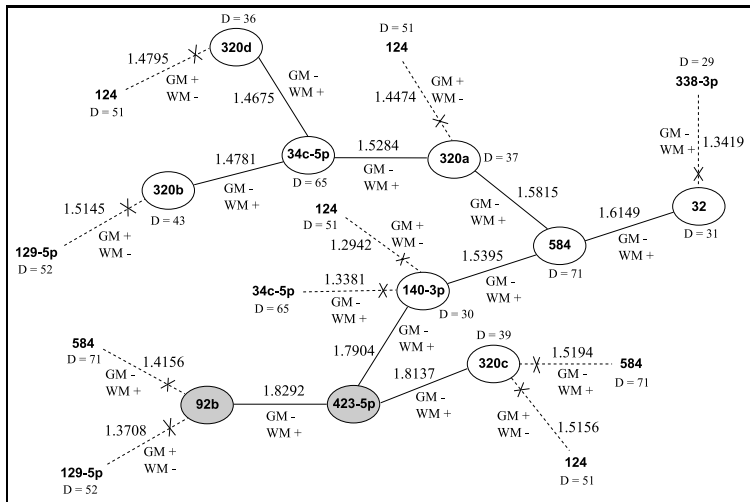

Hypotheses

- Degree: Disease biomolecules avoid hubs
- Modularity: Biomolecules specific to a disease form modules
- Sharing: Diseases having common biomolecules show phenotypic similarity
- Closeness: Causal pathways coincide with the connectors of known disease-subnetworks

Differentially Co-expressed Switching Tree

How to Define an Association as Dense?

Precedings : doi:10.1038/npre.2012.7118.1 : Posted 3 Apr

density = $17/21 \sim 0.81$

minimum participation density = $2/6 \sim 0.33$

Association density of a vertex

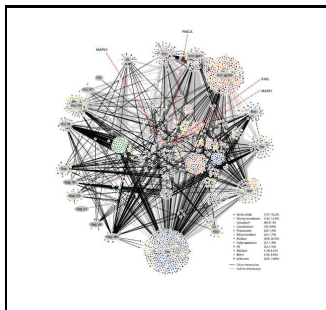

Given a weighted graph $G = (V, E, \Omega)$, the association density, μ_{v_i/V^N} , of a vertex v_i of G with respect to a vertexlet V^N (such that $v_i \notin V^N$), is defined as the ratio of the sum of the edge weights between v_i and each of the vertices belonging to V^N , and the cardinality of the set V^N . Thus, the association density of a vertex v_i with respect to the vertexlet V^N is

$$\mu_{v_i/V^N} = \frac{\sum_{v_j \in V^N} \Omega_{v_i v_j}}{N}.$$

Association density of a vertexlet

The association density of a vertexlet V^N is defined to be the minimum of the association density of every vertex belonging to the vertexlet with respect to the vertexlets of order $(N - 1)$. So, the association density of a

$$\text{vertexlet } V^N \text{ is given by } \mu_{V^N} = \min_{v_i \in V^N} \left(\mu_{v_i/V^N - \{v_i\}} \right).$$

[Ptak, 2008].

DBCLique

DBCLique is a fully connected subgraph $G' = (V'_1, V'_2, E') \subseteq G$ of a directed bipartite graph G such that either $i \in V'_1, j \in V'_2, \forall (i, j) \in E'$ or $i \in V'_2, j \in V'_1, \forall (i, j) \in E'$.

Precedings : doi:10.1038/npre.2012.7118.1 : Posted 3 Apr

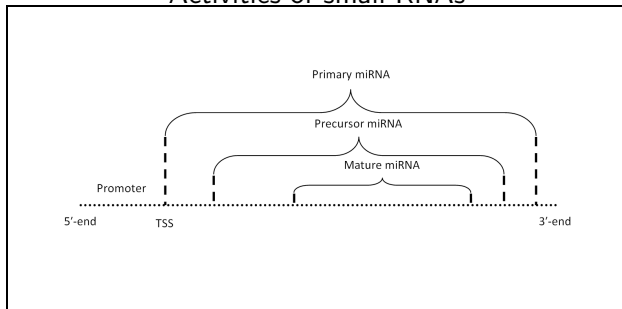

| | Endogenous | Exogenous |
|-----------------------|-------------------|------------------|
| TF combinations | complex | simple |
| Path length | long | short |
| TF outdegree | Low | High |
| Significant motifs | FFLs | single input |
| TF interconnectedness | High | Low |

Activities of small RNAs

Transcriptional regulation of miRNAs

From Networks to Personalized Medicine

Drugs and Biomarkers

How?

- Prepare integrative network models
- Correlate network dynamics and states to the phenotype and patient disease data
- Identify potential multi-node signatures

A test case of cancer metastasis is proposed pursuing the 'seed and soil' principle [Erler, 2009].

More focus on aberrations and pathways

- Identify the genetic aberrations and the master regulators that drive proliferation, survival, metastasis, and drug resistance
- Model the adaptive/feedback mechanisms that thwart the efficacy of potent drugs
- Predict additional target pathways for combinatorial drug treatment
