**Objective:** To investigate the effect of illness on preterm infant's hypothalamus-putituary-adrenal axis, we measured the concentration of cortisol, aldosterone and ACTH.

**Methods:** Ninety preterm infants were divided into two groups: gestational age  $(GA) \ge 34$ weeks' and GA < 34weeks'. We measured serum cortisol, aldosterone and ACTH within 72 hours after birth, day 7 and day 14.

## **Results:**

- (1) The serum cortisol concentration on severe illness was higher than that on mild illness.  $GA \ge 34$ weeks', the cortisol concentration on severe illness infants was significantly higher than mild ill infants within 72 hours (t=-2.263, P=0.029). GA < 34 weeks', the cortisol concentration on severe illness infants was significantly higher on the day 14 (t=-2.913, P=0.006).
- (2) The cortisol concentration was significantly decreased on the day 7 and day 14 than that within 72 hours in the  $GA \ge 34$ weeks' (F = 4.679, p = 0.012);
- (3) The cortisol concentration on death infants was significant higher than that on survivors on the day 14.
- (4) When the cortisol concentration was above the 75<sup>th</sup>, the incidence of mechanical ventilation therapy, glucose metabolism disorder, gastrointestinal hemorrhage, severe periventricular intraventricular hemorrhage and brain leukomacia, chronic lung disease, and mortality rate were increased strikingly.

**Conclusions:** The preterm infant already has the ability to response stimuli by regulating cortisol secretion. The cortisol concentration is correlated with the severity of the disease, complications and prognosis.
