Modified  $TiO_2$  nanomaterials are considered to be promising in energy conversion and ferrites modification may be one of the most efficient modifications. In this research, various ferrites, incorporated with various cations ( $MFe_2O_4$ ,  $M = Ni, Co, Zn$ , and  $Sr$ ), are utilized to modify the well aligned  $TiO_2$  nanorod arrays (NRAs), which is synthesized by hydrothermal method. It is found that all  $MFe_2O_4/TiO_2$  NRAs show obvious red shift into the visible light region compared with the  $TiO_2$  NRAs. In particular,  $NiFe_2O_4$  modification is demonstrated to be the best way to enhance the photoelectrochemical and photocatalytic activity of  $TiO_2$  NRAs. Furthermore, the separation and transfer of charge carriers after  $MFe_2O_4$  modification are clarified by electrochemical impedance spectroscopy measurements. Finally, the underlying mechanism accounting for the enhanced photocatalytic activity of  $MFe_2O_4/TiO_2$  NRAs is proposed. Through comparison among different transition metals modified  $TiO_2$  with the same synthesis process and under the same evaluating condition, this work may provide new insight in designing modified  $TiO_2$  nanomaterials as visible light active photocatalysts.

In recent years, titanium oxide ( $TiO_2$ ), as a “green” photocatalyst, has attracted lots of attention worldwide due to its low cost, nontoxicity and excellent photochemical stability<sup>1</sup>. However, due to the rapid recombination of photogenerated electron-hole pairs as well as the lack of visible light absorption<sup>2</sup>, the photocatalytic and photoelectrochemical efficiency of pure  $TiO_2$  is quite limited. Pure  $TiO_2$ , with bandgap of *ca.* 3.0 to 3.2 eV, can only be excited under UV light irradiation, which comprises only ~5% of the total solar radiation, so, application of the unmodified  $TiO_2$  in solar energy conversion is far limited<sup>3</sup>. Besides, the excited charge carriers in  $TiO_2$  can recombine quickly and more than 90% of the recombination processes take place in  $10 ns$ <sup>4</sup>, therefore, only a little fraction of the excited carriers can transfer to the surface of  $TiO_2$  and take part in the following photocatalytic process. To make full use of solar energy and reduce the recombination rate, many attempts have been made, such as doping with metal/nonmetal atoms and deposition of metals. Though the aforementioned methods can partly improve the photocatalytic as well as photoelectrochemical activity of  $TiO_2$ , some problems remain unresolved. For example, doped  $TiO_2$  may suffer from thermal instability, photo corrosion, lattice distortion, while metal loading may result in an increase in the carrier-recombination probability<sup>5</sup>. In this case, one of the promising strategies is to couple  $TiO_2$  with other narrow band gap semiconductors, which are capable of harvesting photons in the visible light region. Recently, CdS with a low band gap (*ca.* 2.4 eV) was studied intensively to improve the visible light utilization of  $TiO_2$ . However, its application is also hindered due to the low photostability<sup>6</sup>. In view of this, transition metal ferrites with molecular formula of  $MFe_2O_4$  ( $M = Zn, Co, Ni$ , etc.) go into the vision of researchers considering its outstanding attributes. Firstly, these materials possess an important characteristic of narrow band gap, which could absorb the visible light efficiently<sup>7</sup> and thus promote the photocatalytic reactions. Secondly,  $MFe_2O_4$  has a good electrical conductivity due to the electron hopping process between different valence states of metals in O-sites, which is beneficial for the transfer of charge carriers<sup>8,9</sup>. Furthermore, transition metal ferrites have many intriguing advantages such as well stability against photocorrosion, good superparamagnetic properties, low toxicity, easy preparation, high adsorption ability, low cost, and abundant resources<sup>10–12</sup>. So far, most of the researches are focused on separation of  $TiO_2$  powders from treated water by employing its

magnetic property of transition metal ferrites<sup>13–15</sup>. It is scarce on study of the visible responsiveness of  $\text{MFe}_2\text{O}_4$  to increase utilization of solar energy as well as to enhance the photoelectrochemical and photocatalytic performance of  $\text{TiO}_2$ .

$\text{ZnFe}_2\text{O}_4$ , with a relatively small band-gap (*ca.* 1.9 eV)<sup>16</sup>, is the most frequently studied to modify  $\text{TiO}_2$  in enhancing the photoelectrochemical capacity. Yuan et al. observed that the  $\text{ZnFe}_2\text{O}_4/\text{TiO}_2$  nanocomposite is more effective as a photocatalyst in the phenol degradation than pure  $\text{TiO}_2$ . However the mechanism of the enhanced photoactivity of the  $\text{ZnFe}_2\text{O}_4/\text{TiO}_2$  composite is still needed to be further understood<sup>17</sup>. Furthermore, the following researches proposed similar theory to explain the role of  $\text{ZnFe}_2\text{O}_4$  in enhancing photoactivity of  $\text{TiO}_2$ <sup>18,19</sup>, that is, the adoption of  $\text{ZnFe}_2\text{O}_4$  makes the  $\text{ZnFe}_2\text{O}_4/\text{TiO}_2$  composite could use visible light, and the good match of band edges between  $\text{ZnFe}_2\text{O}_4$  and  $\text{TiO}_2$  is in favor of charge carriers separating effectively. Reports about other  $\text{MFe}_2\text{O}_4$  modified  $\text{TiO}_2$ , such as  $\text{NiFe}_2\text{O}_4/\text{TiO}_2$ ,  $\text{Mn}_{0.5}\text{Zn}_{0.5}\text{Fe}_2\text{O}_4/\text{TiO}_2$ ,  $\text{MgFe}_2\text{O}_4/\text{TiO}_2$  and  $\text{CuFe}_2\text{O}_4/\text{TiO}_2$  all show higher photoelectrochemical and photocatalytic performance<sup>20–23</sup>. It seems that  $\text{MFe}_2\text{O}_4$  is such a promising material to improve the photoelectrochemical and photocatalytic performance of  $\text{TiO}_2$ . However, the comparison among the photoelectrochemical and photocatalytic performances of transition metal ferrites modified  $\text{TiO}_2$  reported in the literatures is extremely difficult, because the experimental conditions were very different, such as catalysts synthesis process, light irradiation wavelength, reactor geometric configuration, catalyst loading and so on. Moreover, the origin and the crystalline structure of  $\text{TiO}_2$ , which strongly affect its electronic and photoactivity, are also different. Therefore, the same condition should be taken into consideration when assessing the real effect of transition metal ferrites on the photoactivity of  $\text{TiO}_2$ , such as using the same bare  $\text{TiO}_2$  as the starting material, taking the same procedure to modify  $\text{TiO}_2$  by transition metal ferrites, and finally evaluating their performances with unified standards.  $\text{NiFe}_2\text{O}_4$ ,  $\text{CoFe}_2\text{O}_4$ ,  $\text{ZnFe}_2\text{O}_4$  and  $\text{SrFe}_2\text{O}_4$  are four common transition metal ferrites which have been frequently studied with their magnetism, but except for  $\text{ZnFe}_2\text{O}_4$ , the other three are not common in modifying  $\text{TiO}_2$  to enhance its photoactivity, therefore, we select the four as research objects, making a comparison between the common one ( $\text{ZnFe}_2\text{O}_4/\text{TiO}_2$ ) and the uncommon ones ( $\text{CoFe}_2\text{O}_4$ ,  $\text{ZnFe}_2\text{O}_4$  and  $\text{SrFe}_2\text{O}_4$  modified  $\text{TiO}_2$ ).

In addition to incorporate other materials to modify  $\text{TiO}_2$ , structural design is another important method to enhance the photoactivity of  $\text{TiO}_2$ . One-dimensional (1D) nanostructure such as nanowire, nanotube, nanorod have attracted lots of attention due to the unique physical and chemical properties. 1D  $\text{TiO}_2$  nanomaterials possess all the typical features of  $\text{TiO}_2$  nanoparticles<sup>24</sup>. Electron diffusion length (up to  $\sim 100 \mu\text{m}$ ) can be prolonged by using vertically aligned 1D nanostructures and excited electrons can easily pass along 1D nanostructure to the transparent conducting oxide electrode<sup>25,26</sup>, which facilitate charge transfer and promote charge separating efficiently<sup>20,27</sup>. However, the relatively low specific surface area on a smooth surface of 1D nanostructures may decrease the absorption ability and a single crystal phase of 1D nanostructures may pose certain constraints on the photoelectrochemical performance<sup>24,28</sup>. Fortunately, these disadvantages can be surmounted by introducing the second phase, i.e., doping metals/nonmetals or forming heterojunctions. Among 1D nanostructures, 1D nanorod arrays with large area can be easily obtained by hydrothermal method, which is facile, economic and controllable<sup>29</sup>. Therefore, coupling the traits of one-dimensional  $\text{TiO}_2$  nanorods ( $\text{TiO}_2$  NRAs) and visible light responsive  $\text{MFe}_2\text{O}_4$  nanoparticles seems to be a promising way to enhance the solar energy conversion efficiency of  $\text{TiO}_2$ .

To the best of our knowledge, there is few systematic research on the photoelectrochemical and photocatalytic capacity of various  $\text{MFe}_2\text{O}_4$  modified one-dimensional  $\text{TiO}_2$  NRAs so far. In this study, large area uniform  $\text{TiO}_2$  NRAs were synthesized hydrothermally and ferrites containing various cations ( $\text{MFe}_2\text{O}_4$ ,  $\text{M} = \text{Ni, Co, Zn, and Sr}$ ) were utilized to modify the as-prepared  $\text{TiO}_2$  NRAs. The morphology, crystalline structures and optical properties as well as photoelectrochemical performances of  $\text{TiO}_2$  NRAs and  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRAs were investigated. Moreover, the photocatalytic activities of the  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRAs were evaluated in the degradation of Cr(VI) aqueous solution under visible light irradiation. Finally, the underlying photocatalytic mechanism was discussed.

## Results and Discussion

Figure 1(a) displays the XRD patterns collected from the  $\text{TiO}_2$  NRAs and  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRAs. It can be seen that the  $\text{TiO}_2$  NRAs and  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRAs all features the characteristic peaks at  $2\theta = 36.078^\circ$ ,  $62.750^\circ$ ,  $69.010^\circ$  and  $69.795^\circ$ , indicative of rutile  $\text{TiO}_2$  (PDF NO. 21–1276). Other peaks can be attributed to the diffraction of FTO substrate. There is no typical diffraction peaks of  $\text{MFe}_2\text{O}_4$  after modification, which may be owing to the low content of  $\text{MFe}_2\text{O}_4$ . The content of  $\text{MFe}_2\text{O}_4$  will be discussed in the following SEM characterization.

In order to further examine the phase composition of the samples and confirm the existence of  $\text{MFe}_2\text{O}_4$ , Raman spectroscopy was employed. As is shown clearly in Fig. 1(b), there are three Raman peaks at 241.4, 445.6 and  $609.5 \text{ cm}^{-1}$  for all samples, which are assigned to the Raman active modes of rutile<sup>30</sup>. This result indicates that the rutile phase dominates the crystalline structure of the samples, which is in accordance with the XRD result. However, the Raman peak corresponding to  $\text{MFe}_2\text{O}_4$  is not discernable due to the low content of  $\text{MFe}_2\text{O}_4$ . The peak at  $117 \text{ cm}^{-1}$  is due to plasma emission of the  $\text{Ar}^+$  laser<sup>31</sup>.

In order to further confirm the existence of  $\text{MFe}_2\text{O}_4$ , XPS measurement was carried out. The XPS survey spectra are shown in Fig. 2(a). The peaks located at the binding energies of *ca.* 458–464 eV, 529–531 eV, 711–725 eV and 284–288 eV in all samples are ascribed to the Ti 2p, O 1s, Fe 2p, and C 1s, respectively. On the other hand, these  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRAs materials also show their characteristic peaks located between 850 and 875 eV (Ni 2p) for  $\text{NiFe}_2\text{O}_4/\text{TiO}_2$  NRAs, 781 and 796 eV (Co 2p) for  $\text{CoFe}_2\text{O}_4/\text{TiO}_2$  NRAs, 1021 and 1044 eV (Zn 2p) for  $\text{ZnFe}_2\text{O}_4/\text{TiO}_2$  NRAs, and 134 eV (Sr 2p) for  $\text{SrFe}_2\text{O}_4/\text{TiO}_2$  NRAs.

As is shown in Fig. 2(b), the Ni 2p peaks of  $\text{NiFe}_2\text{O}_4/\text{TiO}_2$  NRAs consist of two characteristics of Ni 2p<sub>3/2</sub> (855.72 eV) and Ni 2p<sub>1/2</sub> (874.12 eV)<sup>32</sup>, indicative of the presence of  $\text{Ni}^{2+}$ . Similar to the Ni 2p peaks in  $\text{NiFe}_2\text{O}_4/\text{TiO}_2$  NRAs, the Co 2p XPS spectra recorded from the  $\text{CoFe}_2\text{O}_4/\text{TiO}_2$  NRAs sample, containing Co 2p<sub>3/2</sub> (781.03 eV,  $\text{Co}^{2+}$  in Tet-site) and Co 2p<sub>1/2</sub> (796.67 eV,  $\text{Co}^{2+}$  in Tet-site), indicate that  $\text{Co}^{2+}$  exists in the  $\text{CoFe}_2\text{O}_4/\text{TiO}_2$  NRAs according to the literature reports<sup>33</sup>. For the  $\text{ZnFe}_2\text{O}_4/\text{TiO}_2$  NRAs, the recorded Zn 2p XPS

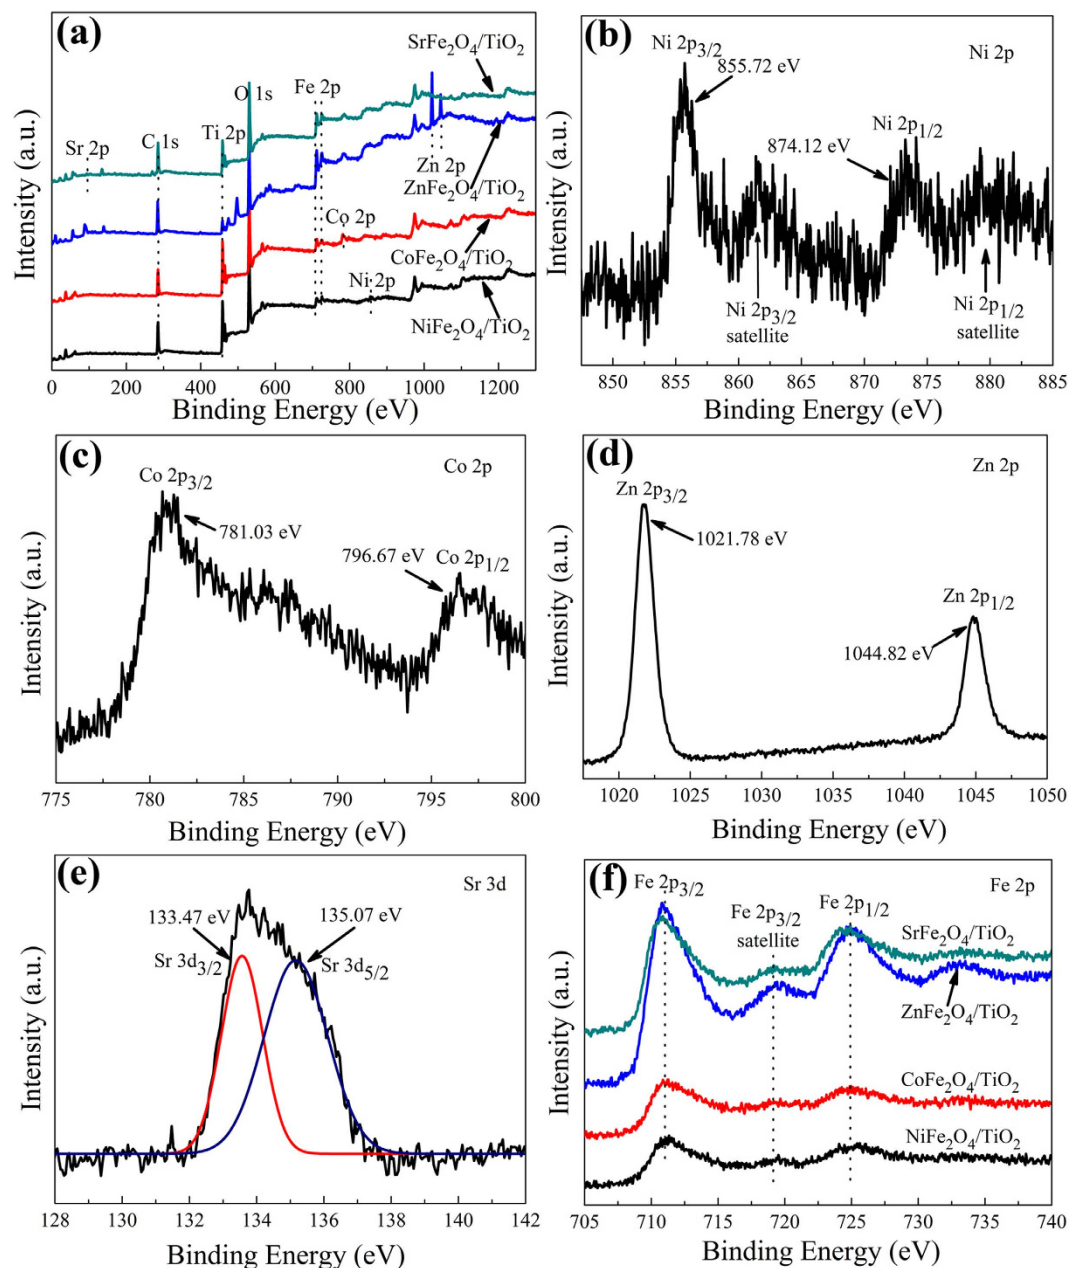

**Figure 1.** (a) XRD patterns and (b) Raman spectra for TiO<sub>2</sub> NRAs and MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs.

spectra indicate that Zn<sup>2+</sup> exists in the ZnFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, which is also consistent with literature reports<sup>34,35</sup>. Furthermore, the manganese valences were determined by the position of the multiplet splitting of Sr 2*p* peaks, the positions of Sr 2*p*<sub>3/2</sub> and Sr 2*p*<sub>1/2</sub> were all assigned to Sr<sup>2+</sup>. As for high-resolution XPS spectra of Fe 2*p* in Fig. 2(d), one can see that the peaks at *ca.* 711.6 eV and *ca.* 724.9 eV can be attributed to Fe 2*p*<sub>3/2</sub> and Fe 2*p*<sub>1/2</sub> for Fe<sup>3+</sup>, respectively, which reveals the oxidation state of Fe<sup>3+</sup> in the MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> heterostructure<sup>33,36</sup>.

The high resolution XPS spectra of Ti 2*p*, O 1*s*, and C 1*s* are shown in Fig. 3. The Ti 2*p* spectra, as presented in Fig. 3(a), all show the main peak located at *ca.* 458.5 eV and *ca.* 464.2 eV, which can be attributed to Ti 2*p*<sub>3/2</sub> and Ti 2*p*<sub>1/2</sub> in TiO<sub>2</sub>, respectively<sup>37</sup>. It is clear that the O 1*s* spectra of these MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs samples can be deconvoluted into two components centered at *ca.* 529.8 eV and *ca.* 531.4 eV using two Gaussian curve fittings {Fig. 3(b)}, The components at the lower and higher binding energy side can be assigned to the crystal lattice oxygen of TiO<sub>2</sub> and MFe<sub>2</sub>O<sub>4</sub> and chemisorbed oxygen in a defective lattice site (i.e. -OH), respectively<sup>32,38–41</sup>. It is suggested that the hydroxyl group can capture the photogenerated holes and form highly reactive hydroxyl free radicals, which plays an important role in enhancing photocatalytic activity<sup>18</sup>. The high resolution XPS spectrum of C 1*s* is shown in Fig. 3(c). The primary peak located at *ca.* 284.6 eV is assigned to C–C/C–H bonds from adventitious carbon<sup>42</sup>, while the peaks at *ca.* 286.2 eV and *ca.* 288.4 eV can be attributed to the formation of carbonate species, resulting mainly from CO<sub>2</sub> adsorption<sup>38,43–45</sup>. Especially, the peak at 288.4 eV can be ascribed to the Ti–O–C structure in carbon doped TiO<sub>2</sub> by substituting some of the lattice titanium atoms<sup>46–48</sup>. Interestingly, carbon doping is beneficial to light absorption capability as well as absorption of organic molecules to some extent<sup>24,25</sup>.

The SEM images of the bare TiO<sub>2</sub> NRAs and MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs are shown in Fig. 4. It is noteworthy that, after MFe<sub>2</sub>O<sub>4</sub> modification as shown in Fig. 4(c–f) from the top view images, the samples have no obvious changes in morphology compared with the bare TiO<sub>2</sub> NRAs in Fig. 4(a), which indicates that the deposited MFe<sub>2</sub>O<sub>4</sub> nanoparticles are of extremely fine size. The vertically or slantingly aligned TiO<sub>2</sub> nanorods arrays, with diameter of 60–120 nm and length of 2.2 μm, are grown homogeneously on FTO substrate with rectangular cross section. In order to measure the content of MFe<sub>2</sub>O<sub>4</sub> in MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs heterojunction, energy dispersive x-ray spectrum (EDS) analysis was carried out. The results, shown in Fig. 4(g–j), are obtained from collecting the EDS data in red square region of the MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs in Fig. 4(c–f), respectively. It is confirmed that Ni, Co, Zn and Sr are present in NiFe<sub>2</sub>O<sub>4</sub>, CoFe<sub>2</sub>O<sub>4</sub>, ZnFe<sub>2</sub>O<sub>4</sub> and SrFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs, respectively. Indeed, only a trace amount of Ni, Co, Zn and Sr can be observed in these samples.

Furthermore, structural characterizations of the MFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> nanorods were investigated by TEM. Figure 5(a) shows the TEM image of the bare TiO<sub>2</sub> nanorod. Essentially, the diameter of the bare TiO<sub>2</sub> nanorod under TEM observation is consistent with the SEM result. It can be seen clearly that the bare TiO<sub>2</sub> nanorod is very

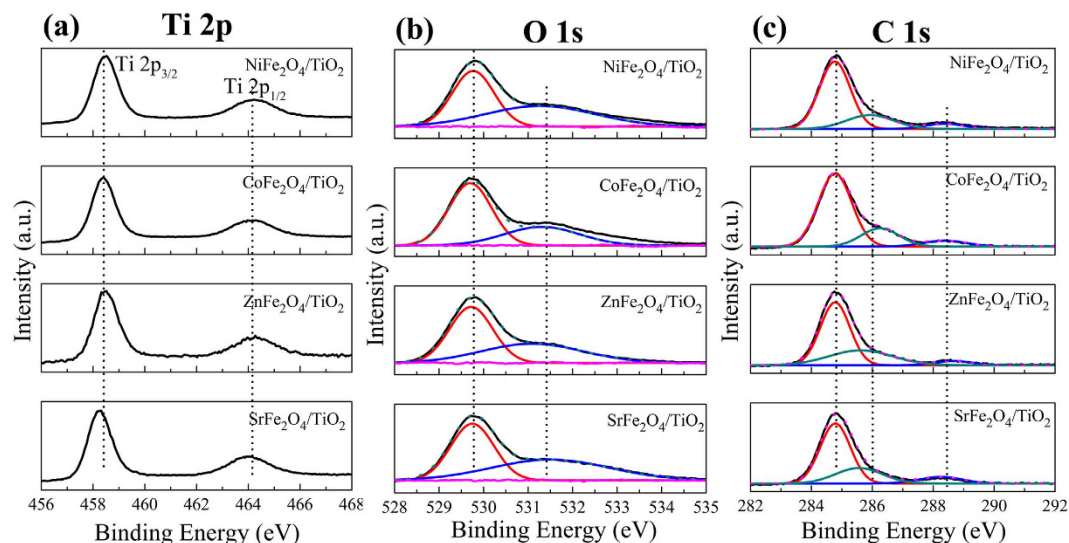

**Figure 2.** (a) XPS survey spectra of  $MFe_2O_4/TiO_2$  NRAs and high-resolution XPS spectra of (b) Ni 2p, (c) Co 2p, (d) Zn 2p, (e) Sr 2p and (f) Fe 2p.

smooth. After  $MFe_2O_4$  modification shown in Fig. 5(c), the nanorod surface becomes rough, and the ultrafine  $NiFe_2O_4$  particles, with diameter of *ca.* 3~5 nm as shown in Fig. 5(d), are uniformly deposited on the nanorod. In addition, the high resolution HRTEM image gives lattice fringes of about 0.481 nm and 0.251 nm, corresponding to the *d* (111) and *d* (311) space of  $NiFe_2O_4$ , respectively. Analysis of TEM was also applied to  $CoFe_2O_4$ ,  $ZnFe_2O_4$  and  $SrFe_2O_4$  modified  $TiO_2$  NRAs (shown in Supplementary Fig. S1), and all show the same morphology. i.e., the smooth surface of  $TiO_2$  nanorod become rough after  $MFe_2O_4$  modification. The corresponding lattice fringes of  $CoFe_2O_4$ ,  $ZnFe_2O_4$  and  $SrFe_2O_4$  are shown in Figure S1(b,d,f), respectively.

The optical absorption spectra of  $TiO_2$  NRAs and  $MFe_2O_4/TiO_2$  NRAs are shown in Fig. 6. All samples exhibit typical UV absorption ( $\lambda < 380$  nm). It is noteworthy that, compared with bare  $TiO_2$  NRAs, all  $MFe_2O_4/TiO_2$  samples exhibit strong light absorption in a wide region from 380 nm to 900 nm, which can be attributed to the intrinsic band gap absorption of  $MFe_2O_4$ . However, unlike other pure  $TiO_2$ , tiny absorption of the as-prepared  $TiO_2$  sample in the visible light range can be observed. There are two reasons accounting for this abnormal phenomenon, one is the scattering of light caused by the nanorod arrays, and the other is the impurity doping during the hydrothermal and sintering process<sup>49-51</sup>. The absorption capacity of  $CoFe_2O_4/TiO_2$  NRAs is the biggest, followed by  $ZnFe_2O_4$ ,  $SrFe_2O_4$  and  $NiFe_2O_4$  modified  $TiO_2$  NRAs sequentially. The corresponding band gaps are calculated from the plots of  $E_g = 1240/\lambda$  by extrapolating the linear portion of absorbance to the wavelength

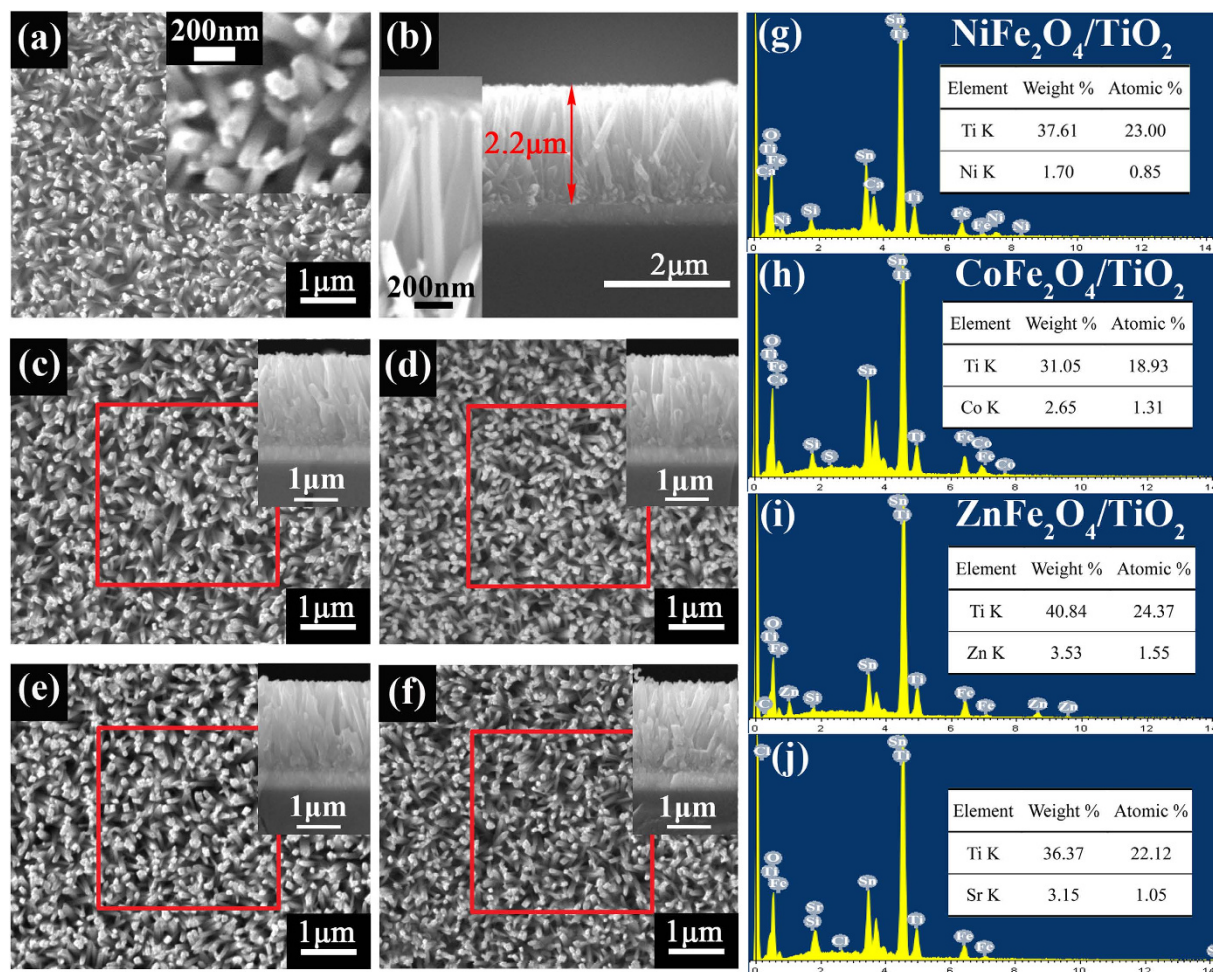

**Figure 3.** High-resolution XPS spectra of (a) Ti 2p, (b) O 1s and (c) C 1s.

axis where absorbance is zero<sup>52</sup>. As is shown in Fig. 6, the steep absorption edge of the bare TiO<sub>2</sub> NRAs locates at about 410 nm, corresponding to band gap ( $E_g$ ) of about 3.02 eV. MFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs samples all exhibit red-shift with smaller band gaps compared with bare TiO<sub>2</sub> NRAs, and the  $E_g$  is ca. 1.84 eV, 1.63 eV, 1.81 eV and 1.53 eV for NiFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, ZnFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, SrFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, and CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, respectively.

To evaluate the effect of MFe<sub>2</sub>O<sub>4</sub> modification on the photoelectrochemical properties of TiO<sub>2</sub> NRAs, the photocurrent intensity versus potential ( $I-V$ ) and photocurrent density versus time ( $I-T$ ) measurements of MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs were performed. The  $I-V$  characteristics of MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs are shown in Fig. 7(a). The photocurrent density in dark can be neglected for all samples. Under visible light irradiation, the photocurrent density of bare TiO<sub>2</sub> NRAs varies little with increase in bias potential, while the photocurrent density of MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs increases significantly at more positive bias potentials, except for CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs with only a slight increase. For example, at bias potential of 0.4 V vs. Ag/AgCl, the photocurrent density of NiFe<sub>2</sub>O<sub>4</sub>, ZnFe<sub>2</sub>O<sub>4</sub> and SrFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs is 6.13, 3.31 and 2.81  $\mu\text{A}/\text{cm}^2$ , respectively, while the photocurrent density of CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs is only 0.95  $\mu\text{A}/\text{cm}^2$ , which is far lower than that of other MFe<sub>2</sub>O<sub>4</sub> modified samples, and only a little higher than that of the bare TiO<sub>2</sub> NRAs (0.46  $\mu\text{A}/\text{cm}^2$  at 0.4 V vs. Ag/AgCl). It is reported that the more negative open circuit potential ( $V_{oc}$ ) means better charge carrier separation and electron accumulation in semiconductor-semiconductor heterojunctions<sup>53–56</sup>. After MFe<sub>2</sub>O<sub>4</sub> modification,  $V_{oc}$  for NiFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, ZnFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs and SrFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs is  $-0.323$ ,  $-0.156$  and  $-0.133$  V, respectively, which becomes more negative than that of the bare TiO<sub>2</sub> NRAs ( $-0.121$  V), except for CoFe<sub>2</sub>O<sub>4</sub> modified one ( $-0.117$  V). From the varying trend of  $V_{oc}$ , one can see that MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs (M = Ni, Zn and Sr) heterojunction facilitates the separation and transfer of the charge carriers, while CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs is not favourable for charge carriers separation. Figure 7(b) plots the  $I-T$  characteristics of the MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs. It is observed that all the samples exhibit a quick response to the on/off of the incident light, and the current density of MFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs shows an enhancement compared with that of bare TiO<sub>2</sub> NRAs. NiFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs displays the biggest photocurrent density of ca. 4.13  $\mu\text{A}/\text{cm}^2$ , followed by ZnFe<sub>2</sub>O<sub>4</sub>, SrFe<sub>2</sub>O<sub>4</sub> and CoFe<sub>2</sub>O<sub>4</sub> modified ones, with 1.73, 1.68 and 1.01  $\mu\text{A}/\text{cm}^2$ , respectively. The enhancement induced by CoFe<sub>2</sub>O<sub>4</sub> modification is relatively low, only 0.4  $\mu\text{A}/\text{cm}^2$  higher than that of bare TiO<sub>2</sub> NRAs (0.61  $\mu\text{A}/\text{cm}^2$ ). The changing trend of  $I-T$  result is consistent with the  $I-V$  characteristics of the MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs.

Though all MFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs samples exhibit a broader and stronger absorption than the bare TiO<sub>2</sub> NRAs (see Fig. 6), only NiFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs possesses a significant enhancement in PEC performance. Very limited improvement for CoFe<sub>2</sub>O<sub>4</sub> modification may result from the inefficient separation of photoexcited charge carriers. This phenomenon is due to the fact that the conduction band (CB) of CoFe<sub>2</sub>O<sub>4</sub> is more positive than that of TiO<sub>2</sub>, while the valence band (VB) of CoFe<sub>2</sub>O<sub>4</sub> is more negative than that of TiO<sub>2</sub><sup>41,57</sup>, which is not favour in carriers separating.

To investigate the photocatalytic capacity of the MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, experiments were carried out for Cr(VI) photoreduction under visible light irradiation. The concentration changes are detected by the absorption peak (365 nm) of Cr(VI) in the UV-vis spectrum. The photodegradation results are shown in Fig. 7(c). After irradiation for 180 minutes, little Cr(VI) was reduced without catalyst (the reduction rate is only 3.8%). Under the same condition, only 45.1% of Cr(VI) was reduced when bare TiO<sub>2</sub> NRAs was used as a photocatalyst. However, the photoreduction capacity of NiFe<sub>2</sub>O<sub>4</sub>, ZnFe<sub>2</sub>O<sub>4</sub> and SrFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs are enhanced greatly (94.18%, 94.086% and 92.39%, respectively), reaching the same level. This may be attributed to the function of citric acid serving as a sacrificial electron donor to quickly consume the photogenerated holes<sup>19</sup>, thus greatly promote charge separation and further improve photocatalytic reactions. Unfortunately, CoFe<sub>2</sub>O<sub>4</sub> modification makes the photocatalytic degradation rate of Cr(VI) even lower. The following reason may account for this abnormal

**Figure 4.** SEM images of (a) the bare TiO<sub>2</sub> NRAs, (b) the cross section image of the bare TiO<sub>2</sub> NRAs, (c) NiFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, (d) CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, (e) ZnFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs and (f) SrFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs. The insets of (c–f) are the corresponding cross section images. (h,i,g,k) are the EDS results of the red square region in (c–f), respectively.

phenomenon. Even though CoFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs can be excited more easily under visible light irradiation, and then generates more charge carriers, the recombination rate of CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs seems to be higher than that of the bare TiO<sub>2</sub> NRAs which can be deduced from the *V*<sub>oc</sub> changes, thus leading to the lower photocatalytic capacity of CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs.

In order to clarify the enhancement in the phototectochemical and photocatalytic capacity of TiO<sub>2</sub> NRAs after MFe<sub>2</sub>O<sub>4</sub> modification, it is important to figure out the separating and transferring efficiency of the charge carriers, so electrochemical impedance spectroscopy (EIS) measurements were conducted. As shown in Fig. 7(d), except for CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, other MFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs samples all have a smaller arc radius compared with that of the bare TiO<sub>2</sub> NRAs. It is generally assumed that the smaller arc radius on the EIS Nyquist plot suggests a more effective separation of the photogenerated electron-hole pairs and a faster interfacial charge transfer<sup>38,58</sup>. From the EIS spectra, it can be seen clearly that NiFe<sub>2</sub>O<sub>4</sub>, ZnFe<sub>2</sub>O<sub>4</sub> and SrFe<sub>2</sub>O<sub>4</sub> modified TiO<sub>2</sub> NRAs have a smaller arc radius than the bare TiO<sub>2</sub> NRAs. It means that the charge carriers separate and transfer more effectively in NiFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, ZnFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs and SrFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs, thus leading to the significant enhancement of the phototectochemical and photocatalytic capacity of the modified TiO<sub>2</sub> NRAs. While the arc radius of CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs is even bigger than that of the bare TiO<sub>2</sub> NRAs, suggesting lower separating rate of charge carriers in CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs and thus resulting in the limited enhancement of the phototectochemical capacity and even decrease in photocatalytic performance. This EIS result of CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs is in accordance with the *V*<sub>oc</sub> value of CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs in the *I*-*V* curves as well as the deduction from the band matching between CoFe<sub>2</sub>O<sub>4</sub> and TiO<sub>2</sub> in previous literature, that is, the CoFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> heterojunction is not conducive to effective separation of carriers.

Photocatalytic schematic of Cr(VI) by MFe<sub>2</sub>O<sub>4</sub>/TiO<sub>2</sub> NRAs is shown in Fig. 8. Under visible light illumination, MFe<sub>2</sub>O<sub>4</sub> is effectively excited to generate electrons and holes. Because the conduction band of MFe<sub>2</sub>O<sub>4</sub> is more positive than that of TiO<sub>2</sub>, the excited electrons can quickly transfer from MFe<sub>2</sub>O<sub>4</sub> to the conduction band of TiO<sub>2</sub>, whereas the generated holes accumulate in the valence band of MFe<sub>2</sub>O<sub>4</sub>. Consequently, the excited electron/hole

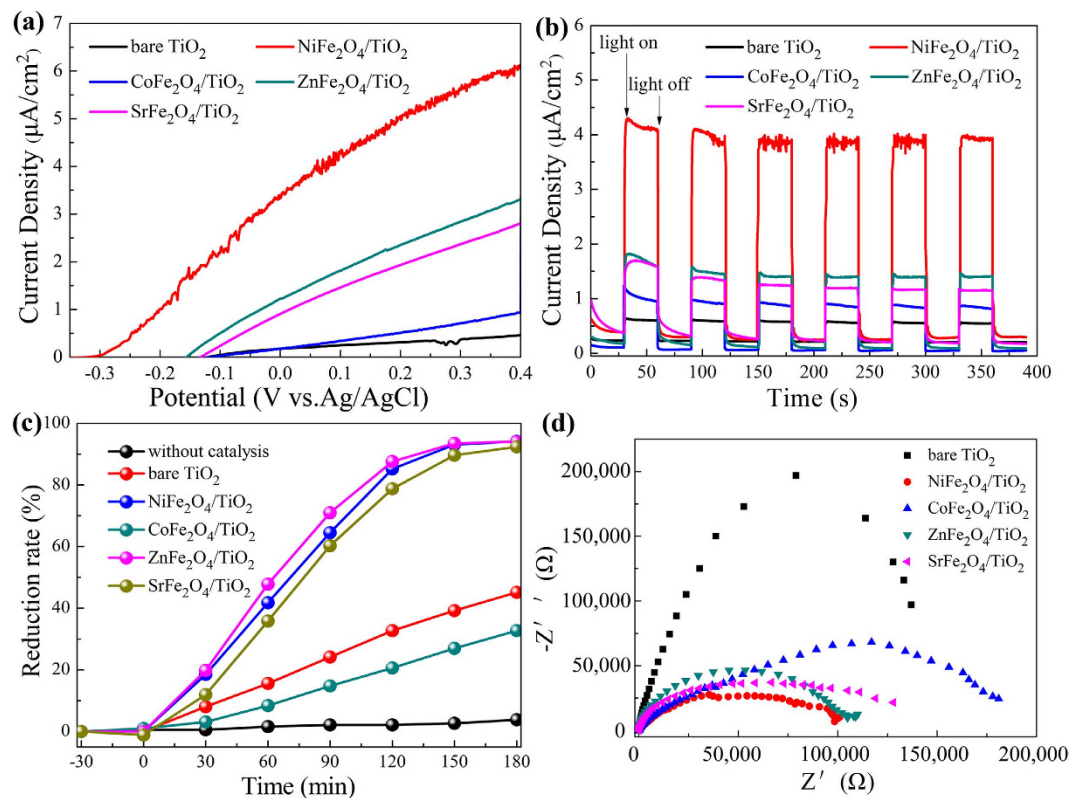

**Figure 5.** (a,b) TEM images of  $\text{TiO}_2$  NRAs, (c,d) TEM images of  $\text{NiFe}_2\text{O}_4/\text{TiO}_2$  NRAs.

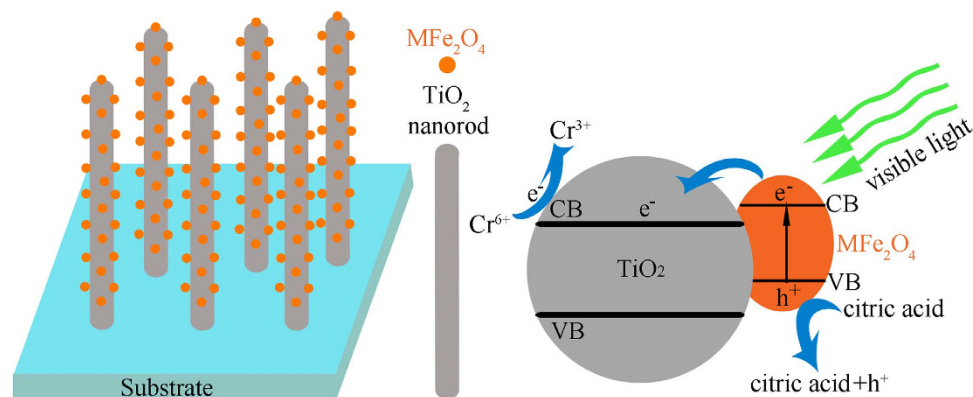

**Figure 6.** Absorption spectra of  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRAs. The dash lines are the extension of the linear portion of absorbance.

pairs could be separated effectively, which contributes to the improvement of photoelectrochemical properties of  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRAs, except for  $\text{CoFe}_2\text{O}_4/\text{TiO}_2$  NRAs. Due to the efficient separation of the photogenerated electrons and holes by  $\text{MFe}_2\text{O}_4$  modification, the lifetime of the charge carriers are prolonged, leading to an efficient oxidation-reduction reaction, so the photodegradation activity can be enhanced. When the photoreduction is carried out in the presence of citric acid, it can quickly consume the accumulated holes in the valence band, and thus the electrons in the conduction band have enough time to function with the  $\text{Cr(VI)}$  in the aqueous solution.

## Conclusions

The effect of different ferrites ( $M\text{Fe}_2\text{O}_4$ ,  $M = \text{Ni}, \text{Co}, \text{Zn}$  and  $\text{Sr}$ ) modification on improving the photoelectrochemical and photocatalytic properties of  $\text{TiO}_2$  have been probed. By changing the incorporated cations in the  $M\text{Fe}_2\text{O}_4$ , we have found that  $\text{NiFe}_2\text{O}_4$  modification can greatly enhance the photoelectrochemical and photocatalytic performance of  $\text{TiO}_2$  NRAs, while  $\text{CoFe}_2\text{O}_4$  has relative limited effect. Compared with the bare  $\text{TiO}_2$  NRAs, the photocurrent density of  $\text{NiFe}_2\text{O}_4/\text{TiO}_2$  NRAs is twelve-fold higher in the I-V curve at  $0.4 \text{ V}$  vs. Ag/AgCl. Under visible light irradiation, the  $\text{Cr}(\text{VI})$  photoreduction rate of  $\text{NiFe}_2\text{O}_4/\text{TiO}_2$  NRAs achieves one-fold higher than that of the bare  $\text{TiO}_2$  NRAs. The EIS measurement provides a clearer understanding of the role that  $M\text{Fe}_2\text{O}_4$  have in photogenerated charge carriers effectively separating and transferring. Except for  $\text{CoFe}_2\text{O}_4/\text{TiO}_2$  NRAs, other  $M\text{Fe}_2\text{O}_4$  modified  $\text{TiO}_2$  NRAs have more effective separation and transfer of the charge carriers, thus leading to the difference in the photoelectrochemical and photocatalytic performance of  $M\text{Fe}_2\text{O}_4$  modified  $\text{TiO}_2$  NRAs. The obtained results point that the visible active  $M\text{Fe}_2\text{O}_4$  modification may be a promising way to improve  $\text{TiO}_2$  for applications in photocatalytic activity as well as in photoelectrochemical conversion with solar light.

## Methods

**Materials synthesis.** All reagents used were analytical grade chemicals and used without further treatment.

**Synthesis of  $\text{MFe}_2\text{O}_4$  modified  $\text{TiO}_2$  nanorod arrays.** Aligned  $\text{TiO}_2$  NRAs were vertically grown on transparent fluorine-doped tin oxide (FTO) substrates by the hydrothermal method. Deionized water (DI, 10 mL) was mixed with hydrochloric acid (36.8 wt%, 10 mL) and stirred for 10 min before tetrabutyl titanate (98%, 0.4 mL) was added. When the solution was stirred until clear clarification, it was transferred to a Teflon-lined stainless steel autoclave. Clean FTO substrates were immersed with the conducting side face down. The autoclave was put in an oven at a temperature of 150 °C and was taken out from the oven after 5 h. After the autoclave was cooled to room temperature, the FTO substrate was rinsed with DI water and dried naturally at room temperature. The final area of the nanorod arrays was approximately 4.5 cm<sup>2</sup>.

For the preparation of  $\text{ZnFe}_2\text{O}_4/\text{TiO}_2$  NRAs, briefly, zinc nitrate and iron nitrate were dissolved in DI water at room temperature to form a mixture, the as-prepared  $\text{TiO}_2$  NRAs were soaked in the  $\text{Fe}(\text{NO}_3)_3$  and  $\text{Zn}(\text{NO}_3)_2$  mixed solution (with concentrations of 0.25 M and 0.125 M, respectively) for 1 h, followed by dipping in DI water for 5 s. Afterwards the nanorod arrays were dried in air for 24 h and then annealed at 500 °C in air for 2 h with heating and cooling rates of 5 °C·min<sup>-1</sup>. The  $\text{MFe}_2\text{O}_4/\text{TiO}_2$  NRs (M = Ni, Co and Sr) were prepared using the same method by replacing the zinc nitrate with other nitrate.

**Characterization.** The surface morphology was obtained with a scanning electron microscopy (SEM, VEDAIXMUINCN) equipped with an energy dispersive X-ray spectroscopy (EDS) system. The film microstructure was further characterized by transmission electron microscopy (TEM). X-ray diffraction (XRD, PANalytical) with Cu-K $\alpha$  ( $\lambda = 0.15401$  nm) was operated at 40 kV and 40 mA in a 2 $\theta$  range of 20–80° at a scanning speed of 5° min<sup>-1</sup> to characterize the crystal structure. Raman spectra were recorded at room temperature using a inVia Reflex Raman spectrometer under Ar<sup>+</sup> (532 nm) laser excitation. The optical properties were probed by a UV–vis spectrophotometer (UV1800, Shimadzu) with a FTO substrate as a blank. X-ray photoelectron spectroscopy (XPS) was obtained using a ESCALAB 250Xi (The binding energy of the XPS spectra was calibrated with the reference to the C 1s peak at 284.8 eV.)

**Photoelectrochemical and photocatalytic measurement.** photoelectrochemical measurements were performed in a 250 mL quartz cell using a three-electrode configuration, including the prepared samples as working electrode, a Pt foil as counter electrode, a saturated Ag/AgCl as reference electrode, and 0.5 M  $\text{Na}_2\text{SO}_4$  aqueous solution as an electrolyte. The working electrode was illuminated within an area of about 1.5 cm<sup>2</sup> at zero bias voltage versus the Ag/AgCl electrode under solar-simulated (AM 1.5 G filtered, 100 mW·cm<sup>-2</sup>, CEL-HXF300) light sources with a UV cutoff filter (providing visible light with  $\lambda \geq 420$  nm). The electrochemical impedance spectroscopy (EIS) measurements were recorded by employing an AC voltage of 5 mV amplitude with the initial potential at 0.4 v (vs. Ag/AgCl) over the frequency range from 100 kHz to 100 mHz without light illumination.

The Cr(VI) photoreduction was performed in a quartz cell. In the photoreduction experiments, 15 mL of aqueous solution containing 20 mg·L<sup>-1</sup> of  $\text{K}_2\text{Cr}_2\text{O}_7$  and 85 mg·L<sup>-1</sup> of citric acid was used. The citric acid served as a sacrificial electron donor. Prior to irradiation, the photocatalyst (area about 6 cm<sup>2</sup>) was immersed into the Cr(VI) solution in the dark for 30 minutes to establish an adsorption/desorption equilibrium. The relative concentration of Cr(VI) in the solution was derived by comparing its UV–vis absorption intensity with that of the initial Cr(VI) solution at 365 nm. The light source was a 300 W xenon lamp with visible light illumination of 26.5 mW·cm<sup>-2</sup>.
