Our paper identified 6-methyl-2-*p*-tolylaminobenzo[*d*]oxazin-4-one (URB754; Specs) as a monoacylglycerol lipase (MGL) inhibitor that enhances hippocampal depolarization-induced suppression of inhibition (DSI). However, in subsequent tests of non-commercial URB754, we failed to replicate these results, suggesting that a bioactive impurity was present in the commercial material. We have identified this impurity as bis(methylthio)mercurane (**Supplementary Results** online). Because this compound interacts with multiple targets, we tested another MGL inhibitor, methylarachidonylfluorophosphonate (MAFP), which prolonged DSI (**Fig. 1**), confirming that monoacylglycerol lipase contributes to the termination of DSI, as others have reported¹. Another generation of endocannabinoid metabolism inhibitors is needed to test this hypothesis further.

Figure 1 Effects of MAFP on DSI in hippocampal CA1 pyramidal cells. Top, traces from a representative experiment showing the effects of vehicle (ethanol, 0.00003%) or MAFP (Tocris, 45 nM) on the transient reduction of spontaneous inhibitory postsynaptic potentials (IPSCs) elicited by a depolarizing stimulus (arrow). Scale bars, 100 pA, 5 s. Bottom left, averaged time-course of DSI after administration of vehicle (solid squares) or MAFP (open squares). Bottom right, DSI area in the first 30 s after stimulus application was significantly larger in MAFP-treated than in control slices.
