tematic matters is rather less detailed than in the English "Zoological Record," the notices of anatomical and physiological papers are fuller, and the student will always find indications of the direction in which to look for information on other subjects. The conductors of these useful Reports have always been in the habit of delaying their publication until the literature of each year could be analysed as completely as possible, and in the present issue we have only the particulars of the contributions to entomological knowledge published during the years 1867-68. The Insecta proper are reported upon by M. F. Brauer of Vienna, whilst Prof. Gerstäcker confines his labours to the Myriopoda, Arachnida, and Crustacea.

The Science and Art Department

BELIEVING your columns to be at all times open for the discussion of matters connected with Science and Art teaching, I venture to offer a few remarks on the administration of the above-named Department.

Since the arrival of the results of the last May examination, the teachers have been enabled to make up their claims for payment, and there has been a great outcry from all parts of the country on account of the serious reduction that has taken place in the amounts the teachers are entitled to claim for their work. This reduction arises from the operation of the last alteration by the Department of the scale of payments on results, the full effect of which was not felt until this year.

Many objections were raised at the time the minute was issued (in the latter part of 1869), especially to its being introduced after the commencement of the work of the session, and in deference to these remonstrances it was modified in its application to the May examinations of 1870, and its full operation deferred till the May just past. When I say just past I am speaking after the manner of the Department, for they are so far behind that the Annual Report for the Session of 1869-70 has not yet been received by the committees here.

Now I venture to submit that this reduction in the scale of payments is likely to have a very injurious effect on the spread of education in Science. In many cases, especially in small towns, and where a teacher has a class in only one or two subjects, the amount of payment to be received is so small as to give rise to the apprehension that such classes will be given up, because of the utter inadequacy of the payment to remunerate a teacher for the time and trouble spent in the work of instructing them. To give an illustration, I have just been informed of an instance where a teacher has had to proceed fourteen miles by rail to give his lectures to a class, and the result of the recent examination is that he received absolutely nothing from the Department in respect of this class, all those of the students who passed being persons of the middle classes.

When in conjunction with such facts as these we read that the payment for instruction in Science and Art in 1870 was 17,000*l.* less than in the previous year, there seems great reason for the complaints of the teachers, and one must, I think, come to the conclusion that the Department has proceeded too far in the direction of economy to be conducive to efficiency or to the continued spread of scientific instruction.

If the present scale is to be retained, I think the suggestion of a writer in the *Daily News* recently, that the system of payment by results alone should be modified, is worthy of consideration. The teacher often has the greatest amount of trouble with those students who just miss obtaining a certificate, and in these cases the master receives nothing at all for the labours of the session. It would be more encouraging to the teacher if a small payment was made for those students who have attended the required number of class lectures, although they may not be able to pass the examination for proficiency. Of course, there should be safeguards provided against the abuse of such a rule, say, by excluding from its operation all such as are unable to attempt a stated proportion of the questions propounded.

Even under the present arrangements I have seen many

students sit idle the greater part of the evening, or leave the examination room as soon as permitted to do so by the regulations, through not being able to attempt to answer more than two or three questions.

With regard to another matter of which complaint has been made, viz., the recent minute of the Department imposing fines on Committees who ask for a larger number of papers than they require, I must say I cannot see the reasonableness of the complaint. At the last May examination in Plymouth, one school alone (according to the printed list issued by the department) sent up a requisition for 714 papers in the various subjects of Art and Science, while the total number of papers worked by pupils of that school, and by strangers whose papers were asked for through its committee, was only 339—less than half. If this case is at all a sample of what was occurring in the country generally, and the issue of the minute leads me to think such must have been the case, I consider it was quite time for something to be done to prevent such wholesale waste. Of course in all schools there will be a certain number who will shrink back at the last moment, after having given in their names for the examination, and this being fairly provided for, I do not see anything in this regulation that efficient schools and committees should complain of.

Elementary Geometry

I HAVE to thank the Editor of *NATURE* for inserting my letter, and Mr. Wilson for writing so fully. I was not aware when I wrote, that Mr. Wilson had himself published an elementary book on geometry. He has modestly omitted to refer to it; but I have seen it, and it appears to me a suggestive book for a teacher. He acknowledges himself unable to recommend one suited to boys, for laying the foundation of geometry.

Mr. Wilson's advice seems rather suited to teachers of geometrical drawing than of mathematics. Of course it is essential that a boy should know what measuring means; but scales of measurement have no essential connexion with geometry. Nevertheless, I entirely agree with him that much trouble must be taken to teach the metrical system, especially as it is not likely to be popularly used in England, at least while our children are living. To purchase a simple metrical rule is by no means an easy task. They are not kept, that I can find, at any ordinary instrument makers in London, Oxford, or Cambridge.

With your permission I will say what I think is required in a book for boys. It must, to a certain extent, be suitable for being committed to memory, as Euclid is. No child is capable of taking in a subject, especially if it involves logical thought, except by very slow degrees; and must at the beginning commit much to memory which he does not comprehend. What I write will appear, to those who do not know children, to involve a most vicious principle in teaching; but it is, nevertheless, a fact. Our new book must, therefore, contain all the steps of every proof in full, and no symbols must be used. In the next place, it must not be artificial. It seems agreed that the use of compasses ought to be of the nature of a postulate, which would at once get rid of such propositions as the second and third of Euclid. There can be no reason for excluding the idea of the motion of a point, since in practice no figures can be drawn except by moving the pencil's point. It appears then that, having once got over the difficulty of defining a point, a line should be "the path of a point," a definition which would easily lead on to the doctrines of curvature and tangents; and a straight line would be that which does not alter its direction (virtually Euclid's definition); and, as in Mr. Wilson's book, parallel straight lines, those whose directions are the same.

It seems to me that it would be better to retain Euclid's definition of proportion, only converting it into a *test* of proportion; because the constructions founded upon it are so convenient for geometrical purposes; and if it be superseded by the algebraical mode of treating the subject, reasoning on incommensurable quantities must be introduced.

In fine, the book which is to supplant Euclid appears to be at present a desideratum. When it appears, it probably must be the work of more heads than one, if it is to be generally accepted among teachers.

A FATHER

THE circumstances attending my own introduction to geometry lead me to doubt whether a long course of practical geometry is
