

William Gault's detailed "Observations on the Geology of the Black Mountains," a coloured diagram is given. The Appendix contains papers by Mr. Joseph Wright on "Recent Foraminifera of Down and Antrim," and by Messrs. Swanston and Lapworth on the "Correlation of the Silurian Rocks of Co. Down."

THE Twentieth Report of the East Kent Natural History Society is, on the whole, satisfactory. It contains abstracts of several good papers read at the meetings. The Society has ninety-three members.

EXCAVATIONS in the "Dragon Cave" at Mixniz, Styria, have been already noticed (NATURE, vol. xviii. p. 618). The diggings made in June, 1878, by the Anthropological Society of Gratz, have brought to light some bones bearing indistinct marks of cutting and percussion. Above the stalagmitic layer over the hearth-stuff some bones were found, in loam, well preserved, but probably derived from an older site. They are greenish, and partly of an intense bluish-green tint; and Prof. C. Doelter finds that their composition approaches that of turquoise [bone-turquoise?]. A full account by Prof. R. Hoernes will be found in the *Proc. Imp. Geol. Instit. Vienna*, August 31, 1878.

THE additions to the Zoological Society's Gardens during the past week include a Yellow Baboon (*Cynocephalus babouin*), from West Africa; two Ring-tailed Lemurs (*Lemur catta*), from Madagascar, presented by Mr. G. A. Shaw; a Green Monkey (*Cercopithecus callitrichus*), from West Africa, presented by Mr. J. Williams; a Common Fox (*Canis vulpes*), British, presented by Mr. Sutton Sharpe; a Woodcock (*Scolopax rusticola*), European, presented by Messrs. E. and W. H. Davis; a Common Swan (*Cygnus olor*), European, presented by Capt. Marx; a Ring-tailed Lemur (*Lemur catta*), from Madagascar, deposited; an Ocelot (*Felis pardalis*), from America; a Cereopsis Goose (*Cereopsis nova-hollandia*), from Australia; three Yellow-winged Blue Creepers (*Coccyz cyanea*), from South America, purchased.

ON HELIOTROPISM IN PLANTS

THE heliotropic phenomena in plants form the subject of a monograph by Herr Wiesner, the first part of which has been recently communicated to the Vienna Academy. The following outline from the *Anzeiger* of the Academy will give an idea of some of the fruits of the author's researches on this important subject.

The first section treats of the history of the subject. In the second section the author studies the influence of light on heliotropism. The experiments were made in the light of a gas flame which burned under a constant pressure with a uniform intensity (luminous power = 6.5 spermaceti candles). The unit for the measurement of the light-intensity was the strength of this flame at the distance of one metre. It was found that in heliotropism three cardinal points of light-intensity are to be distinguished; an upper limit, a lower limit, and between the two an optimum of light intensity. Thus with decreasing intensity of light the strength of the heliotropic effect increases to a certain point, and beyond this point decreases. The lower limit referred to coincides with the lower limit of light-intensity for the stoppage of growth in length, while the upper limit does not coincide, or only occasionally coincides, with the upper limit of light-intensity for growth in length, for in the case of plants very sensitive heliotropically it lies higher, and in less sensitive plants lower, than the upper limit for growth in length. The mode of arrangement of the experiment in gas-light did not permit of determining in all cases the limiting values of the light-intensities; thus, for example, the upper limit for the heliotropism of etiolated shoots of *Salix alba*, and of the hypocotylous portion of the stem of *Viscum album*, and the lower limit for the heliotropism of the growing stem of vetch could not be ascertained. The former lies above 400, the latter far below 0.008. The optima were found to lie between 0.11 (the growing stem of the pea) and 6.25 (etiolated shoots of *Salix alba*). Both with gas-light and with natural light it was ascer-

tained that beyond a certain intensity no growth in length occurs.

The third section treats of the relations between the refrangibility of the light rays, and the heliotropic effects. The experiments were made partly in the objective spectrum, partly in varieties of light, got by sending white light through coloured solutions. . . . It was proved that portions of plants very sensitive heliotropically, e.g., growing stems of *Vicia sativa*, undergo curvatures in all kinds of light, even in ultra-red and ultra-violet, with the exception of yellow. The maximum of the heliotropic force of light lies at the boundary between violet and ultra-violet; a second (smaller) in the ultra-red. From both maxima the power of the rays to produce heliotropism decreases gradually on to the yellow. Portions of plants little sensitive heliotropically, are no longer influenced by orange, or by red and green, or even (in the case of etiolated shoots of *Salix alba*) by ultra-red rays. The yellow rays quite stop the heliotropism, for, e.g., in pure red a quicker and stronger heliotropism occurs than in a light which gives yellow besides red.

In the fourth section experiments are described on the joint action of (positive and negative) heliotropism and (positive and negative) geotropism. It is here shown, *inter alia*, that, in the case of plants very sensitive heliotropically, the geotropism is, at the optimum of light-intensity, apparently extinguished, even in strongly geotropic organs; further, that in many organs (growing stem of the pea), the heliotropic and geotropic powers of curvature disappear simultaneously; in others, however (stems of cress), the younger portions of the stem are more strongly heliotropic than the older, and the oldest after-growing portions of stem no longer show bendings in the light, but, through drawing action on one side (the heliotropic overhanging point of the stem), show apparently heliotropic curvatures chiefly due to growth, which are then counteracted by negative geotropism.

The arguments which go to prove that heliotropism is due to the phenomenon of unequal growth upon unequally-lit sides of an organ are set forth in the next section, and proof is offered that, for heliotropism as well as for growth in length, free oxygen is necessary.

The last chapter furnishes proof that the conditions for heliotropism remain constantly the same during its course, and coincide with the conditions for growth in length; further, that heliotropism (and the same holds good for geotropism) occurs as a phenomenon of induction. In this chapter it is also shown that when light induces heliotropism in an organ, a fresh heliotropic or geotropic induction meets with resistances, and can only come into action after extinction of action of the first; and that successive impulses of light and gravity, of which each by itself is capable of producing certain effects, do not have their actions added together when the effects that should be obtained separately are in the same direction, e.g., one and the same side of the organ is helped in its growth in length.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, December 5.—"On a Machine for the Solution of Simultaneous Linear Equations," by Sir William Thomson. Let B_1, B_2, \dots, B_n be n bodies each supported on a fixed axis (in practice each is to be supported on knife-edges like the beam of a balance).

Let $P_{11}, P_{21}, P_{31}, \dots, P_{n1}$ be n pulleys, each pivoted on B_1 ;
 $P_{12}, P_{22}, P_{32}, \dots, P_{n2}$ " " " B_2 ;
 $P_{13}, P_{23}, P_{33}, \dots, P_{n3}$ " " " B_3 ;

" $C_1, C_2, C_3, \dots, C_n$, be n cords passing over the pulleys;
 " $D_1, P_{11}, P_{12}, P_{13}, \dots, P_{1n}, E_1$, be the course of C_1 ;
 " $D_2, P_{21}, P_{22}, P_{23}, \dots, P_{2n}, E_2$, " " C_2 ;

" $D_1, E_1, D_2, E_2, \dots, D_n, E_n$, be fixed points;
 " $l_1, l_2, l_3, \dots, l_n$ be the lengths of the cords between D_1, E_1 , and D_2, E_2, \dots and D_n, E_n , along the courses stated above, when B_1, B_2, \dots, B_n , are in particular positions which will be called their zero positions;

Let $l_1 + e_1, \dots, l_2 + e_2, \dots, l_n + e_n$ be their lengths between the same fixed points, when B_1, B_2, \dots, B_n are turned through angles x_1, x_2, \dots, x_n from their zero positions;

(11), (12), (13), ... (1*n*),
 (21), (22), (23), ... (2*n*),
 (31), (32), (33), ... (3*n*),

Capt. Butler, of H.M.'s 83rd Regt., on the Mekran Coast.—Dr. Day, F.Z.S., exhibited and made some remarks on some jaws of Indian sharks belonging to the genera *Galeocerdo* and *Carcarias*.—The Secretary called attention to an error which had been made in reference to the collection of butterflies from Billiton, reported on by Messrs. Godman, Salvin, and Druce, in the last part of the Society's *Proceedings*. The collection had been made and forwarded to England by Herr J. G. F. Riedel, of Koepang.—Mr. Sclater communicated some further particulars respecting the occurrence in Lancashire of the specimen of the black-throated Wheatear (*Saxicola stapanina*) exhibited at the last meeting of the Society.—Prof. A. H. Garrod, F.R.S., read a paper on the conformation of the thoracic extremity of the trachea in the birds of the order Gallinæ.—A communication was read from Dr. A. Günther, F.R.S., containing the description of some reptiles from Midian, collected by Major Burton. Amongst these were two new snakes proposed to be called *Echis decorata* and *Zamenis elegantissima*.—Mr. H. Seebohm pointed out the character of a new *Sylvia* from Abyssinia, proposed to be called *Sylvia blanfordi*, after Mr. Blandford, by whom it was obtained during the Abyssinian Expedition.—Mr. H. Seebohm also read notes on the identity of the birds which had been named *Horornis fortipes*, *Neornis assimilis*, *Horreites robustipes*, *H. brunneus* and *H. pallidus*, and proposed to reduce them to one species under the name *Cetia fortipes*.—Mr. Martin Jacoby read descriptions of some new species of Phytophagous Coleoptera from Central and South America.

Anthropological Institute, November 26.—Mr. John Evans, F.R.S., president, in the chair.—The Rev. John Robbins, D.D., was announced as a Member.—Mr. Worthington G. Smith exhibited a series of flint implements from the valley of the River Lea.—Mr. A. L. Lewis read a paper on the evils arising from the use of historical national names as scientific terms. The propositions which he endeavoured to establish were: 1. That there were at the first population of Europe certain primitive races, of which three are particularly described. 2. That these races are so mixed that at the present day the representatives of them appear not only in most European nations, but in the same families and among children of the same parents. 3. That notwithstanding this mixture and the effects which it must permanently have, racial characters display an astonishing permanence. 4. That this mixture, being so slow in its effects and yet having become so general, has probably been at work for a very great length of time—so great that the peoples to whom the earliest history introduces us were probably nearly as much mixed as those of the present day. 5. That it is desirable to discontinue the use of political names of those peoples as ethnic names, and to employ others, based on the physical characteristics of the individual. 6. That while physical characteristics are the only basis for a true division into races, yet in the practical application of this division the influence upon [individuals of different races of a community of language, custom, history, or tradition must not be lost sight of, although these things do not prove community of race, but only the contact at some time or other of the races to whom they are now common.—The director read a paper by Prof. Daniel Wilson, LL.D., on some American illustrations of the evolution of new varieties of men. In the mingling of different races in America, so complex and varied, all subjected to the influences of climate and social habits, and all mingling in blood in a greater or less degree with the native red races, hybridity had resulted on a great scale. The process had already been developed sufficiently long to afford important indications of the evolutions of permanent hybrid varieties. A specimen is to be seen among the tribes of the half-breeds in Manitoba, as it were in the process of evolution; while sheltered within the remote Arctic regions man can be studied among the Esquimaux in conditions closely analogous to those which are ascribed to a post-pliocene, if not to a pre-glacial period. In the abrupt collision of the civilised races of Europe with the American aborigines, it had always been taken for granted that the latter were doomed to inevitable extinction, and that the land would be peopled with the purely civilised races of the world. There is no question, however, that from an early date there have been intermarriages between Europeans and the American races. A growing feeling is manifesting itself in the United States and Canada that the Indian population is not doomed to extinction, and that a much larger amount of healthy intermarrying and consequent absorption has existed than unobserving critics had any conception of, and the native Indian element is a factor in the population of the New

World destined to exercise an enduring influence on the ethical character of the Euro-American races.

CAMBRIDGE

Philosophical Society, November 4.—The following communications were made to the Society:—The physical constants of hydrogenium, by Prof. Dewar, Part 2. This paper is a continuation of an investigation into the physical constants of hydrogenium. The first part appeared in the *Transactions* of the Royal Society of Edinburgh, vol. xxvii., and had reference to the specific gravity, specific heat, and coefficient of expansion of the occluded hydrogen. These observations led to the conclusion that the specific gravity was independent of the amount of condensed gas, and had a mean value of 0.62. This result has been confirmed by the subsequent experiments of Troost and Hautefeuille, and what is very remarkable, they deduce an identical value for the density of hydrogen from observations on the hydrides of potassium and sodium. The specific heat, relatively to palladium, of the condensed hydrogen, appeared to vary inversely as the charge, but taken relatively to successive charges was nearly constant, and had the value 3.4, which is identical with that of gaseous hydrogen at constant pressure. The coefficient of the cubical expansion of the alloy is about twice that of palladium, and that of the hydrogen in its compressed state not more than three times that of mercury. This communication deals with the thermo-electric relations and conductivity of hydrogenium. It is shown that the electro-motive force of a junction of hydrogenium palladium is at ordinary temperatures nearly equal to that of an iron copper junction, and that it increases with the temperature according to the general parabolic law, the rate of the increase being, however, greater than iron copper and subject to a regular variation on account of successive heatings. The formation of thermo-electric piles, and of neutral points in a uniform wire of this substance, along with the continuous formation of thermo-electric currents through the application of a hydrogen flame were explained and shown. Experiments on the electric resistance show that it increases directly as the amount of condensed gas.—Studies in spectrum analysis, by Professors Liveing and Dewar. The authors describe the reversal of characteristic lines of rubidium and cesium when the chlorides are heated with sodium in glass tubes in an atmosphere of hydrogen or nitrogen, and a bright light is viewed through the vapours. They remark that the violet lines of rubidium, and the most refrangible of the cesium lines are first seen, and broaden out the most when the temperature rises, contrary to what might have been expected from the analogy of other cases. The absorption lines observed coincided with the bright lines of the metals heated in a flame, not with the lines which they give in a dense electric spark; but the authors obtained spectra similar to the flame spectra by passing sparks from an induction coil without a Leyden jar, between beads of fused chlorides of those metals, although simpler spectra were produced by the more abrupt discharges produced by interposing a Leyden jar. The authors further described absorption spectra produced by magnesium vapour when mixed with hydrogen, potassium, and sodium respectively. That produced by magnesium and hydrogen consisted of a line a little less refrangible than the δ group, and a band rather more refrangible than the δ group, fading away towards the blue. The constant appearance of these absorptions when the vapour of magnesium in hydrogen was observed in a hot iron tube, led to the endeavour to obtain the corresponding luminous spectrum. This they succeeded in doing by taking sparks from an induction coil, without a Leyden jar between magnesium wires in a tube full of hydrogen. It appears that the compound to which this spectrum is due is formed only within a certain range of temperature, and is dissociated at higher temperatures—for the spectrum is scarcely seen at all when a large Leyden jar is used, which may be supposed to have the effect of shortening the time of discharge and increasing the temperature. Further, this compound does not seem to be formed when the pressure of the hydrogen is much reduced. In the case of sodium and magnesium they observed an absorption line in the green not observed in either vapour separately; and when potassium and magnesium were used, a characteristic pair of lines in the red always appeared, and sometimes another line in the blue. The authors have not yet seen these as bright lines. In the course of observations on the spectra of sundry rarefied gases the authors have been led to conclude that electric sparks take a selective course in a mixture of gases, and that the differences in the spectra

observed in different parts of the same tube are probably due to the existence of more than one gas in the tube. Tubes of nitrogen which did not show the lines of hydrogen at all when sparks from an induction coil without a Leyden jar were passed through them, gave strong hydrogen lines when a large jar was interposed. A bulb tube with magnesium wires filled with hydrogen at low pressure gave in one half scarcely any spectrum but the F-line of hydrogen, while the other half gave the spectrum of acetylene. They generally found hydrogen lines and flashes of sodium (no doubt from the glass) in tubes very much exhausted; and they conclude that impurities enter such tubes from sources hitherto unsuspected. Tubes filled with oxygen obtained from silver iodate have been found to give the spectrum of iodine, pointing to the conclusion that chemical reactions occur at very low pressures which are not produced under other circumstances. Generally the authors conclude that the spectrum of a gas in a rarefied state affords the most delicate test of its purity, and that it is to the chemical problem of obtaining pure gases that attention needs to be specially directed.

PARIS

Academy of Sciences, December 9.—M. Fizeau in the chair.—The following papers were read:—New method for determining the flexion of telescopes, by M. Loewy. The principle is to produce in the field, besides the images of the eyepiece and objective (whose position may vary), a third image emanating from the axis of rotation, which, completely independent of the flexion of the tubes, undergoes only a slight displacement due to the auxiliary lens. This image serves as a means of estimating the relative displacement of the two others. (A concavo-convex lens is placed in the axis of the central cube, and on its axis of rotation.)—Examples of calculation of the torsion of prisms with mixtilinear base, by M. de Saint-Venant.—On the binary form of the seventh order, by Prof. Sylvester.—Study on ordinary and compound steam engines, steam jackets, and superheating, according to experimental thermodynamics, (extract), by M. Ledieu. Some observations are here made on neutral spaces and their influence, the restriction of these having been one direction of recent improvement.—On the works of the Saint Gothard tunnel, by M. Colladon. After recounting obstacles which have retarded the work—among others, greatly increased and violent infiltration, and the swelling of a plastic mass of decomposed felspar and gypsum on contact with moist air, exerting tremendous pressure on supports—he gives information about the air compressing and ventilating apparatus and the boring machines. It is expected that about eight years will suffice for the completion of the work. The difference between the first estimated and actual expense will, it is thought, be nearly 100 million francs.—On a series of soundings undertaken by M. Roudaire in view of the formation of the African interior sea, by M. De Lesseps. These soundings will cover about 500 leagues, and will occupy M. Roudaire about six months, after which it will be possible to estimate fairly the expense of the project. M. De Lesseps describes what he saw of that region.—Report on a memoir of Prof. Lawrence Smith on the native iron of Greenland and the dolerite it contains. The reporters recommend insertion of this interesting memoir in the *Recueil des Savants étrangers*.—Diseases of plants caused by *Pero-nospora*; attempted treatment; application to the lettuce-disease, *P. Ganghiformis*, Berk. Memoir by M. Cornu.—M. Werdermann replied to M. Reynier's reclamation of priority with regard to the electric lamp. He maintains that his (W.'s) lamp depends not on the effect of incandescence of a heated carbon, but on an extremely small voltaic arc; the incandescence of a small part of the electrode is merely an inevitable consequence.—On an automatic regulator of currents, by M. Hospitalier. This consists of a one-layer resistance bobbin, having a portion of its wire laid bare, and in contact with a slightly convex distributor connected with an armature before an electro-magnet which is affected by the current to be regulated.—On a small telephonic apparatus, by M. Boudet de Paris (sealed packet opened). This refers to a telephone in the form of a watch, which, with a microphone, gives speech well. M. du Moncel referred to a very advantageous arrangement of a speaking microphone (by M. Boudet de Paris), which he would shortly describe.—On the reduction, in continuous fractions, of a pretty extensive class of functions, by M. Laguerre.—On a point in the history of mathematics, by M. Desbovas.—Theorems on prime numbers, by M. Proth.—On a remarkable specimen of silicuret of iron, by Prof.

Lawrence Smith. This piece is remarkably rich in silicium (about 15 per cent.), and is evidently the product of a blast furnace. There are no such furnaces where it was found, but there are some a few miles away, and about 100 miles from the spot was one which supplied iron having 8 per cent. silicium, and gave up working because of want of demand for such iron. Prof. Smith thinks the piece may have been (exceptionally) produced there. M. Daubrée said industry has never been known to produce an alloy of iron with nearly so much silicium. The highest proportion at the Exhibition was 10 per cent.—On a new acid obtained from camphor, by M. Haller.—On the formation of hexamethylbenzene by the decomposition of acetone, by Mr. Greene.—On normal ethyloxybutyric acid and its derivatives, by M. Duvillier.—On the presence of ytterbium in the sipylite of Amherst, by M. Delafontaine.—Existence of baryta and strontian in all rocks constituting primordial strata; metalliferous veins with gangue of baryta, by M. Dieulafait. He infers from the facts that baryta and strontian have the same origin, viz, the primordial rocks; hence the metalliferous ores (manganese, lead, zinc, &c.), for which baryta serves as gangue, has also this origin.—On the dangers in use of borax for preservation of meat and the reasons why some substances cause meat to lose its nutritive properties, by M. Le Bon. He prescribes, in principle, the use of chemical substances, even the apparently inoffensive salt, for preservation of meat. The most nutritive part of meat is the juice, and this, when the meat is put in saline solution or covered with a salt in powder, makes rapid exchange of its nutritive principles through endosmose. He hints at a new mode of preservation, however, other than cold.—On an artificial pyroxene (diopside), by M. Gruner.—Influence of atmospheric electricity on fructification of plants, by M. Grandean. It greatly stimulates the phenomenon.—On a disease of the coffee-tree observed in Brazil, by M. Jobert.—On the diffusion of heat by leaves, by M. Maguene.—On the power of absorption of water by wood, by M. Mauméné. The property varies (for different woods) between 9.37 and 174.88 per cent. of the absolutely dry wood; the latter figure was obtained with chestnut.—On a scientific balloon ascent of October 31, by M. Tridon.
