The tamping was blown out of three or four of the holes which I saw operated upon, and this is certainly not what would be called an "extremely rare" occurrence. At the same time it did not appear to affect the final result in any way.

I said nothing about the probability of the process failing or succeeding in its application to the mining of shales, iron ores, &c., and stated no conclusion in this connection which could in any way be affected by the results of the experiments which Mr. Mosley says are pending.

Science at the Victoria Hall

THE immediate object of the Victoria Hall Committee is to provide healthy amusement in place of the unhealthy sort too often found in places of cheap recreation, and does not appeal specially to scientific men as such. But they have a scheme on hand for next autumn to which I venture to call your attention. They would like to devote one evening in the week for popular lectures, and as a previous experiment they propose to have during October and November a series of very elementary popular addresses on scientific subjects of about half an hour in length, to be introduced in the beginning, or middle, or end of the temperance demonstrations which take place on Friday evenings. It is hoped that an interest in such matters may be awakened in the audience (usually numbering ten or twelve hundred, or during the winter more than this), which assembles at these demonstrations. It is an audience less of artisans than of labourers and costermongers, among whom the demand for scientific teaching must be created as well as supplied. If once it can be shown that such addresses are appreciated, we have good hope of efficient help in carrying them on, but we should be grateful for offers of help in the pioneer course. Dr. W. B. Carpenter, Dr. Richardson, and one or two others have given conditional promises, but we have not yet sufficient names for a long enough series to try the experiment fairly.

To simplify and popularise science to the utmost, without lowering it, is not a task which can be performed by those who have no qualification except goodwill, and as, unfortunately, the Victoria Hall is not yet self-supporting, the committee cannot offer anything like adequate remuneration for the services of competent and therefore busy men. They would gladly be responsible for the expense of providing lime-light, or hiring apparatus for experiments, but beyond this they must appeal to the public spirit and generosity of scientific men.

Communications may be addressed to the Honorary Secretary, Royal Victoria Coffee Hall, Waterloo Road, S.E., or to Miss C. A. Martineau, Walsham le Willows, Bury St. Edmunds.

ONE OF THE COMMITTEE

Spelling Reform

IN your note last week on the United States Spelling Reform Report, there is a slight misapprehension. It is said that the result of adopting a phonetic spelling will be the break-up of the English language. This is quite erroneous. Phonetic spelling simply represents pronunciation, and if the phonetic spelling of London English differs from that of Colonial English it can only be because the pronunciations are different; that is, because the language has *already* broken up. On the other hand, if the pronunciations are the same, the spellings will be the same, and I fail to see how an identical spelling in London and Australia can bring about a disruption.

In the present state of Biblical criticism, I rather wonder that the tower of Babel should be appealed to as evidence of Hebrew thought; but if the Hebrews were really so impressed with the confusion of tongues, and if phonetic spelling is really so conducive to that confusion, then let me ask: Why did the Massorites, with that story before their eyes, go and make the originally phonetic Hebrew alphabet more phonetic still by adding the finest set of vowels that has ever been used? Why, except that they knew, as Prof. Sayce and Dr. Tylor know, and the late Charles Darwin knew, that phonetic spelling is the only thing that preserves language and its history from utter decay.

Possible Sound Organs in Spingid Pupæ

IN recently characterising the pupa of *Sphinx catalpe*, Boisd., for my report as entomologist to the Department of Agriculture,

I was struck with the occurrence on the anterior border of each of the larger movable abdominal joints (viz., abdominal joints 5, 6, and 7) of a peculiar elongate concavity, a structure not mentioned by Westwood, Burmeister, Kirby and Spence, Girard, Clemens, Harris, Graber, or any modern author whom I have been able to consult. There is an approach to it in the pupa of *Ceratonia amyntor*, and it occurs in that of *Sphinx harrisii* in similar position and form as in *S. catalpe*. In *Macrosila 5-maculata* it is somewhat above the spiracles, and that on the fifth abdominal joint has a second larger ridge running around it posteriorly. It does not occur in any of the species of the genera *Sesia*, *Thyreus*, *Darapsa*, *Deilephila*, *Philampelus*, and *Smerinthus* in my collection. It has no internal connection with the respiratory or circulatory systems, and its function is probably sound-producing by friction with the posterior margin of the preceding joint. This organ may, in fact, throw some light on the method by which the noise is produced which the pupa of *Sphinx atropos* is capable of. Unfortunately, I have no pupæ of that species for examination.

I shall be glad to learn from any of your Lepidopterological readers if they are familiar with this structure on any other pupæ or know of any record of it.

Meteorology of the Antarctic Region

IT is well known that on the Antarctic lands perpetual snow descends much lower than in corresponding latitudes of the northern hemisphere. The chief cause of this is, no doubt, the difference of climate due to the preponderance of land in the northern hemisphere and of water in the southern. But there is another cause, of sensible magnitude, which I have not seen mentioned. In high southern latitudes the barometer stands permanently nearly an inch lower than in corresponding northern latitudes, and this must cause a permanently lower temperature in the Antarctic regions. That is to say, a depression of an inch in the barometer corresponds to about 1000 feet of mountain ascent; and any station in the Antarctic region must therefore be as much colder than a corresponding one in the Arctic region, as if the Antarctic station stood 1000 feet higher above the sea-level than the Arctic one.

The cause of the barometric depression in the Antarctic region is probably the centrifugal force of the west winds, or "counter-trades," which, as Maury remarks, surround the South Pole with "an everlasting cyclone on a great scale."

JOSEPH JOHN MURPHY

Old Forge, Dunmurry, Co. Antrim, August 8

RECTOR (whose appeal for help in protecting a granite boulder in his country parish we inserted in No. 663) requests us to acknowledge with many thanks the following contributions:—Saxo, 2s. 6d.; William S. Layman, 2s. 6d.; J. W. A., 5s.

SUN-SPOTS AND MARKREE RAINFALL

BY aid of R. Wolf's series,¹ I have been endeavouring, if possible, to trace the effect of the different state of the sun's surface, as shown by the extent of its spots, on our climate. I distributed the annual rainfall, registered here 1833-1863, into ten classes, according to the corresponding values of "the relative numbers" r , as exhibited in Table I. These relative numbers have been determined by Prof. Wolf from a discussion of the registered number of spots and groups of spots on the sun, and are supposed to be proportional to the area covered by spots on the sun's surface. The mean rainfall M , the average of the thirty-one years, is 37.254 inches. o is the rainfall regis-

¹ "En désignant par g le nombre des groupes de taches nus un jour quel conque sur le soleil, une tache isolée comptant pour un groupe; par f le nombre des taches contenue dans tous les groupes, nombre que j'estime approximativement proportionnel à la surface tachetée; et par k un coefficient dépendant de l'observation et de son instrument, et déduit d'observations correspondantes, en supposant ce coefficient égal à l'unité pour mai et pour le grossissement 64 d'un *Fraunhofer* de 4 pieds, je pose: $r = k(f + 10g)$, et je nomme r le nombre relatif de ce jour. La moyenne de tous les nombres relatifs appartenant à la même année donne le nombre relatif de l'année." R. Wolf, Mémoire sur la Pénurie commune à la Fréquence des Taches Solaires et à la Variation de la Déclinaison Magnétique (Mémoires of the Royal Astronomical Society, vol. xlii., 1877, Part vi).

tered during a certain year —. I tried to reduce the difference $o - M$ (Table II.) by applying to M a constant correction, $10x$, and at the same time a correction ry proportional to the respective relative number. The equations of condition of the form—

$$10x + ry + o - M = 0$$

are exhibited in Table I., the last column of which exhibits the remaining errors, v , *i.e.* the difference between the registered rainfall, o , and the calculated, $C = M - 10x - ry$, after that the quantities x and y had been obtained from the equations of condition by solving them by aid of the method of least squares. It will be remarked that v is far smaller than $o - M$ in Table I., the average of several years, but the comparison from year to year, $o - C$ as exhibited in Table II., shows but a small decrease in the differences. The result is—

$$C = 34.435 + 0.04785r = 37.254 + 0.04785(r - 58.91).$$

TABLE I.

Years: 1800 +	Equations of condition.	v .
56, 55, 33	$10x + 7.4y - 3.35 = 0$	-0.89
43, 34, 44	$10x + 15.2y - 1.89 = 0$	+0.20
54, 57, 42	$10x + 22.3y - 2.87 = 0$	-1.12
45, 41, 53	$10x + 38.4y - 0.23 = 0$	+0.76
63, 52, 58, 35	$10x + 53.3y + 0.84 = 0$	+1.11
46, 62, 40	$10x + 60.8y - 1.07 = 0$	-1.16
51, 50, 61	$10x + 70.2y + 4.04 = 0$	+3.50
39, 59, 60	$10x + 89.5y + 2.52 = 0$	+1.06
49, 47, 38	$10x + 99.0y - 1.99 = 0$	-3.91
36, 48, 37	$10x + 127.0y + 3.71 = 0$	+0.45

TABLE II.

Year.	r .	o . inches.	$o - M$. inches.	$o - C$. inches.

1848	124.9	41.22	+3.97	+0.81
1849	95.4	37.63	+0.38	-1.37
1850	69.8	37.12	-0.13	-0.65
1851	63.2	40.25	+3.00	+2.79
1852	52.7	45.72	+8.47	+8.75
1853	38.5	35.17	-2.08	-1.11
1854	21.0	34.77	-2.48	-0.67
1855	7.7	29.36	-7.89	-5.44
1856	5.1	27.87	-9.38	-6.81
1857	22.9	35.14	-2.11	-0.40
1858	56.2	34.34	-2.91	-2.79
1859	90.3	41.65	+4.40	+2.90
1860	94.8	43.74	+6.49	+4.77
1861	77.7	46.52	+9.27	+8.36
1862	61.0	40.23	+2.98	+2.88
1863	45.4	34.97	-2.28	-1.64

It should be remarked that the receiver of the guage is placed on the top of the library, 16 feet above the ground and 148 feet above mean sea-level. I have placed another guage 6 inches above the ground and 110 feet above the sea, as levelled from bench-mark on observatory wall, and have taken precautions against evaporation from this guage. By comparing the results from the two guages during the last five years, I find that the rainfall registered by aid of the upper guage must be multiplied by 1.2426 in order to indicate the rainfall at 110 feet above sea. The formula properly reduced is therefore—

$$C = 46.292 + 0.05946(r - 58.91).$$

I am only too painfully conscious that this result has been derived from insufficient data, but it might be interesting to see whether it would be confirmed by a similar discussion of a sufficiently extensive register kept at some older observatory.

The average monthly rainfalls are as follows:—

	inches.		inches.
January ...	3.451	July ...	3.284
February ...	2.771	August ...	3.599
March ...	2.485	September ...	3.249
April ...	2.460	October ...	3.881
May ...	2.026	November ...	3.530
June ...	3.044	December ...	3.474

Markree Observatory, July 17

W. DOBERCK

THE NEW REPTILE HOUSE AT THE ZOOLOGICAL SOCIETY'S GARDENS

THE present Reptile House in the Zoological Society's

Gardens adjoining the Lecture Room, is an old wooden building, which in the early days of the Society was used for lions and tigers, and is now in a very bad state of repair. Besides this it is much too small for the present collection of reptiles. The cages which it contains are always over full, while the tortoises are necessarily lodged in a separate house, and the crocodiles are kept in a building properly destined to contain sloths and marsupials. Moreover, most of the compartments in the present Reptile House are accessible only from the front, which renders it inconvenient, not to say dangerous, to open them in the day-time, when the house is filled with sightseers. Under these circumstances, the Council of the Society have determined to construct an entirely new building for the better accommodation of the reptiles at the southern corner of the Gardens, and having obtained the necessary permission of H.M. First Commissioner of Works, will commence operations immediately.

The new Reptile House will be 120 feet long by 60 feet in breadth, with a large porch and double entrance at the front, and keepers' and workers' rooms in the rear. The building will be of brick with coarse-hill stone dressings, the roof of iron, slated on the north slope, and provided with ample skylights on the south slope. The house will face due south. It will be fitted with fixed cages for the reptiles on the north, east, and west, leaving the south side (which will be nearly entirely of glass), available for movable cases (such as are now in use in the Insect House), for the smaller and more delicate objects. There will be a large oval pond for crocodiles in the centre of the building, and two smaller circular ponds on each side of it for other aquatic reptiles. The fixed cages, which will be from thirty to forty in number, will be fronted with plate-glass, and the only means of access to them will be from the keeper's passage in the rear, so that there will be no possibility of the animals escaping into the space occupied by the public.

The new Reptile House, will, it is expected, be completed and roofed in before Christmas, and as the hot-water apparatus will be finished by the same date, it will be possible to dry it thoroughly during the winter, so that the reptiles may be moved into their new quarters early in the ensuing summer.

The designs for the new building have been drawn by Mr. C. B. Trollope, and the contract for its erection has been undertaken by Messrs. Hannen and Holland.

The Society's collection of reptiles consists at present of 57 tortoises, 10 crocodiles, 95 lizards, and 83 snakes. Of the last-mentioned, 10 are large pythons and boas, and 14 belong to venomous species. Besides the reptiles there are 56 Batrachians living in the Gardens, which for the present at least, will be kept along with the reptiles.
