

either he must accept the complete idea of the relativity of all motion, of rotation as well as of translation, as professed by Milton, Mach, and Mr. Love; or else he must follow Newton, Maxwell, and the German writers Streintz and Lange (attacked by Mach in Appendix iv.), and distinguish between the relativity of the motion of translation and the absoluteness of rotation. Euler, it appears, was a waverer, and according to Lange never arrived at any settled and intelligible opinion upon the subject. The first theory appears more analogically complete, but introduces unnecessary complication at an early stage; and stronger arguments than those of Mach, and others that I have yet met with, will be required to convert me to their side of the question.

Science Teaching in Schools.

IN the discussion on the teaching of science, and in the schemes put forward for reorganising this teaching, mathematics has so far been left out of consideration.

At present mathematics is taught for its own educational value, which has been traditional since the time of Plato; only in modern times has its great practical value been recognised. The teaching in schools takes little account, however, of the applications of mathematics, and whatever Prof. Greenhill may say (in his review of Prof. Mach's excellent book), there is still wanting complete harmony between those two points of view; not perhaps in the higher branches of the subject and its applications, but certainly in school teaching.

Boys, and girls too, in public schools are taught the elements of mathematics as if all were expected to become mathematicians, and the practical side is kept out of view. In the modern, or science side, which has been introduced at many schools, one finds too often chiefly those boys who show no talent either for classics or mathematics. Many of these have made little or no progress in Euclid; they cannot grasp the altogether abstract notions and symbols of algebra, and they therefore never come near trigonometry. But they are expected to understand the elements of chemistry, mechanics and physics; and it is instructive to find that they very often do understand a good deal of what is taught under these headings.

Now none of these subjects can be accurately taught—and inaccurate teaching is worse than waste of time—without the introduction of mathematical reasoning. Here we are in a vicious circle: the boys are considered incapable of learning mathematics, and therefore mechanics and physics have to be taught without any more than the most elementary notions of geometry and algebra; hence not much progress can be made.

In my opinion the order of procedure might be reversed. Mathematics might be taught through experimental science. If the boys themselves make, as they should do, experiments where they perform actual measurements, they will learn there are certain laws connecting various quantities; they will see that such laws can be expressed in simple symbols, and they will thus grasp in the concrete form the meaning of a formula or an equation which in the abstract form of pure mathematics remained a mystery to them.

Mathematics could in this manner be made very much easier and more interesting to the majority of boys. Geometry can be treated to a very great extent experimentally by aid of geometrical drawing and a development of the Kindergarten methods; the abstract logic of Euclid can then follow, or it can be treated at the same time.

Trigonometry need not be at once as fully gone into as is generally done, but the definitions of sine, cosine, &c., as names for certain ratios, can be easily and early introduced and made use of at once in mechanics or physics. Here also special experiments may easily be devised where measurements of angles or lines are made, and lines and angles calculated.

To explain fully what I mean I should require a great deal of space; in fact it would be almost necessary to draw up a distinct syllabus for a course on the above lines, or to give at least a great number of examples.

At present I wish only to urge that, while many attempts are being made to improve science teaching, and with it technical education, mathematics should be included, and to express my opinion that this science also allows of experimental treatment.

O. HENRICI.

NO. 1309, VOL. 51]

MR. CRUMP (*vide p. 56*) though adopting a critical form and tone, really endorses the grounds of my suggestion that the Science and Art Department should dis sever itself by an age limit from school science. He is inclined to be especially severe upon the defects of the Government examinations because they are controlled by scientific men, and to excuse the proper school examining boards because they have—according to Mr. Crump—attempted to examine in science without any qualification to do so. But I fail to see why eminent scientific men should be expected to be experts in elementary science teaching, any more than distinguished *littérateurs*, in the art of teaching to read, and it seems to me—in spite of Mr. Crump's "absolute" denial—that examining boards, neither professedly literary nor scientific but professedly educational, are more to blame in following and abetting the Department's premium upon text-book cramming. The fact remains that the London Matriculate ignores practical teaching of any kind, and that the "practical chemistry" of the Locals and College of Preceptors is essentially the same test-tube analysis as the South Kensington examination. Anyone who knows the London Matriculation examination—witness Miss Heath's concluding remark—will appreciate the quiet humour of Mr. Crump's allusion to it as "awakening and developing the powers of observation and reasoning."

H. G. WELLS.

The Explosion of a Mixture of Acetylene and Oxygen.

WITH reference to your note in last week's NATURE, I may say that, whilst the thanks of chemists, and particularly of those whose duty it is to perform lecture-experiments, are due to Prof. Lothar Meyer for once more drawing attention to the dangerously explosive nature of mixtures of acetylene and oxygen, it may be assumed that the facts already known concerning acetylene account sufficiently well for the great violence of the explosion, and hence for the circumstance that the mixture will shatter even the open cylinder in which it is detonated. What M. Berthelot terms the molecular rapidity of the reaction, as distinguished from the rapidity of propagation, in the case of mixtures of acetylene and oxygen is very high. The heat of the reaction, too, is nearly five times as much as in the cases of electrolytic gas and of carbonic oxide, and more than twice as much as that of methane. It is slightly exceeded by that of ethylene, but, on the other hand, the theoretical temperature of the change with acetylene is enormously greater than in the case of any other explosive mixture of gases. The temperature, too, required to initiate the change is, as Prof. Lothar Meyer showed indirectly some ten years ago, much lower in the case of acetylene than in that of the other gaseous mixtures of which he speaks. All the conditions tend to make the duration of the reaction so nearly instantaneous that the initial pressure cannot be far removed from the theoretical pressure, and this is sufficient to smash a much stronger envelope than a glass cylinder, even if the "tamping" be nothing more than the air. Everything we know about acetylene combines to show that it is extremely "sensitive" as an explosive, and that in this respect, as in its destructive action, it resembles mercuric fulminate.

T. E. THORPE.

"Newth's Inorganic Chemistry."

THERE are one or two points in Mr. Pattison Muir's review, upon which I should like to be allowed to say a few words.

Criticising the general plan of the book he says:

"It seems to me that the method of the author is radically wrong. Descriptive statements of facts ought surely, neither to precede, nor to follow, but to accompany the reasoning on these facts whereby general principles are gained."

It is not easy to see how the *descriptive statements of facts*, and the *reasoning on these facts* are to be printed in a book at all, unless one either precedes or follows the other. I can only suppose that my reviewer means, that such theoretical and other considerations as I have included in part i., and have called "introductory outlines," should in his opinion not be collected together either at the beginning or at the end of the book, but should be sprinkled among the descriptive chapters. It seems to me that the plan I have adopted, besides being a
