

There was no moon, the wind was south-west and light—the end of the monsoon; and although the sea was, as a matter of fact, breaking here and there, it appeared a calm white sheet, only disturbed by the displacement waves near the ship and a very occasional breaker elsewhere; showing through it were occasional flashes of the ordinary brilliant phosphorescence. It will therefore be seen that the luminosity of the “white sea” was rather less than that of a breaking wave with the same illumination. A bucket of water drawn showed nothing unusual. Samples with and without alcohol were preserved.

A fireball was thrown overboard, and burnt on the surface of the water; this was done in order to see if any fog or mist was present. There was no indication of anything of the kind.

On the port side of the ship is an aperture through which the surplus water from the bath tanks is constantly ejected, slightly warmed. This water, as it fell on to the sea, appeared much blacker than the sea, and floated for a few seconds as a black mass; unfortunately, the same shoot is used for the ashes at times. But the ejected water is quite white by daylight.

The appearance of the sea lasted about an hour, then faded, then brightened again, and was quite bright at daylight, 4.15 a.m.; so that it was seen throughout a distance of nearly fifty miles. A slight recurrence was observed the following night, when the monsoon was blowing more strongly.

At 3 o'clock on the 22nd, in the midst of the “white sea,” the latitude was $10^{\circ} 35' N.$ and the longitude $63^{\circ} 25' E.$; the temperature of the air was $77^{\circ} F.$, that of the water $77^{\circ} F.$ Specific gravity of the water by ship's instrument No. 1314 = 25.

I shall be glad to hand over the specimens of water to any one interested. JAMES W. BARRETT.

Deep-Sea Dredging, and the Phosphorescence of Living Creatures, at Great Sea Depths.

May I call attention to this most interesting subject, upon which so little is known, and with reference to the exploration of the bottom of tropical seas; *nothing is known*, though there is here a mine of natural history wealth probably of unexampled magnitude. In that interesting work on “The Depths of the Sea,” by Sir Wyville Thomson, published more than twenty years ago, we get a glimpse of a hitherto unworked zoological province, which creates a desire to know more from the richness and beauty revealed, where it would be least expected.

He writes—“We had a gorgeous display of luminosity, coming down the Sound of Skye, while dredging in 100 fathoms.

“The Pavoraria came up, resplendent with a pale lilac phosphorescence, like the flame of cyanogen gas—not scintillating, but constant and sufficiently bright to make every portion of a stem distinctly visible, and the stems were a metre long, fringed with hundreds of polyps; and from the number of specimens brought up, we must have passed through a luminous forest of them.

“Among Echinoderms, *Ophiacantha spinulosa* was one of the prevailing forms, and we were greatly struck with the brilliancy of its phosphorescence. Very young *Ophiacantha* shone very brightly also.

“At 344 fathoms, some of our hauls were taken late in the evening, and the tangles were sprinkled over with stars of the most brilliant uranium green. The light was not constant, nor continuous all over the stars, but sometimes it struck out a line of fire all round the disc; flashing or glowing up to the centre; then that would fade, and the whole five rays of *Ophiacantha spinulosa* would light up at the ends, and spread the fire inwards.

“At 557 to 584 fathoms, many of the animals dredged were most brilliantly phosphorescent. In some places, nearly everything brought up seemed to emit light, and the very mud itself was perfectly full of luminous specks. The Pinnatule, Virgularie, and Gorgonie, shone with a lambent white light, so bright that it showed quite distinctly the hour on a watch.

“The light from *Ophiacantha spinulosa* was a brilliant green, coruscating from the centre of the disc, now along one arm, now along another; and vividly illuminating the whole outline of the star-fish.”

From a depth of 567 fathoms, a beautiful scarlet Urchin, *Echinus microstoma*, was obtained. In the year 1846 Keferstein mentions having seen in Stockholm a Crustacean taken from the

depth of 1400 fathoms, of a bright colour. In 1869 and 1870 dredging was carried down to 2435 fathoms by H.M.'s ship *Porcupine*, and the fact that there is an abundant and characteristic invertebrate fauna at that great depth was placed beyond question; but the bottom of the deep sea that has been fairly dredged, may still be reckoned by the square yard; while every haul of the dredge, hitherto used, has brought to light new and unfamiliar forms.

In the number of NATURE for June 30 of this year, there is a most interesting article on deep-sea fishing by means of a trap, an illustration of which is given. These traps are said to have been used at a depth of three thousand fathoms, with complete success. On one occasion a trap that had been lying on the bottom of the Mediterranean, at 700 fathoms depth, for twenty-four hours, brought up 1198 fish, called *Simenichelys parasiticus*. On another occasion, a new crab, one of the largest ever known, *Geryon affinis*, was brought up, and there were sixty-four specimens of it. All this shows how much remains to be done in this province of natural history. E. L. J. RIDSDALE.

The Injection of Cocaine as a Remedy for Stings.

As no one has answered the question asked by Sir J. F. D. Donnelly in your issue of September 8, will you allow me to say that the hypodermic injection of cocaine, or indeed its use in any form, is never quite free from risk. As with most other drugs there is an element of idiosyncrasy, which sometimes produces unexpected and unpleasant results. I believe these occur more frequently, when the drug is injected, than when it is simply applied to the mucous membrane; and when they do occur, they are very alarming. I know that some dentists have given up the practice of injecting cocaine into the gums before extraction on this account, and having been present once when it was done, I should not consent to it again. What we have to remember with regard to the use of all powerful drugs is this, that a few individuals under all conditions, and nearly all under certain conditions, are specially susceptible to their action, and that we cannot determine *a priori* either the individuals so predisposed, or the conditions which render susceptible those not specially predisposed. These drugs must therefore be used with caution, and not be regarded as wholly innocuous.

I should say the hypodermic injection of cocaine into the tongue is undesirable, and only to be done if the pain is intense or the swelling such as to threaten life, in which case it would probably be useful. I would add that so far as I know no solutions of cocaine keep well. M.D., OXON.

THE GEOGRAPHY OF THE UNITED STATES.¹

THIS volume completes the description of the North American continent with the exception of the United States; but, although an excellent account of the United States, it leaves North America itself still undescribed. The general reader, of course, will not miss what he has not been trained to expect; and, if he leaves the conception of geography as a science capable of systematic study out of account, the professed geographer will find much valuable material collected with discrimination and stated clearly and modestly. Indeed, except for an implication on the first page that the United States are in many respects more civilised than Canada, the English reader will find nothing to disturb his equanimity even in the account of the revolutionary war or the feats of the *Alabama*. Mr. Gannett writes always as a good American, but is ready to recognise the defects of his country when necessary, and careful to buttress all agreeable statements with statistics which more than prove them.

Of the arrangement of the matter it is impossible to speak with the same satisfaction. The chapters do not flow in the natural sequence desirable in a literary work,

¹“Stanford's Compendium of Geography and Travel” (New Issue). North America. Vol. II. “The United States.” By Henry Gannett, Chief Geographer of the United States Geological Survey. Maps and Illustrations. Pp. xvi + 466. (London: Edward Stanford, 1893.)
