

walks round a field and successively plants his staff upright where a change in the directions of the boundary occurs ; at each point the observer at the plane table rules the direction line and marks the distance, repeating the operation for each successive point, so that the survey of the field is made during the time taken by the staff man in walking round the field and making the necessary halts at each point for the observation to be recorded. The scale and view photographed through the plane table instrument is shown in Fig. 3.

The same optical principle has also been employed by Sir Howard Grubb in the construction of a level to be used in making rapid estimates of gradients in road making and laying out property.

The observer sees at the same instant a fiducial mark, the bubble of the level, and an arc marked with degrees projected on to the field of view.

The excellent optical device has also been utilised in the construction of a prismatic compass and a clinometer.

M. HERVÉ FAYE.

ALL who have taken any interest in the advance of science, more particularly in the direction of astronomy and meteorology, will hear with regret of the death of M. Hervé Faye, which sad event was announced last week. A long course of scientific industry has marked his career, and a great distance seems to separate the workers of to-day from the epoch when Faye and many others, whose names are now but a matter of history, laboured strenuously and successfully to make the paths for their successors more easy and of more rapid attainment. Nearly sixty years have passed since M. Faye first came prominently before the world as the discoverer of a comet, to which his name has always been attached, and it will serve to make us appreciate the advance accomplished in one lifetime if we recall the fact that this was the first elliptic comet the period of which was determined by calculation alone, without any assistance drawn from observations made at previous returns. Faye, at that time an assistant in the Paris Observatory, recognised the necessity of computing an elliptic orbit, but the credit of determining the first orbit of considerable eccentricity from a few days' observations belongs to Goldschmidt, who was stimulated to the task by Gauss. Then the information and the methods of the *Theoria Motus* had not filtered through a score of text-books and come into the hands of numberless computers, whose deftness of calculation had been whetted by the discovery of hundreds of asteroids, the orbits of which stood in need of determination.

But it will be rather on his philosophical writings than his scientific observations that the reputation of Faye will rest and be honoured by his countrymen. It may be that to some of his theories a general assent has not been given, and that in some cases later discoveries have modified the views the distinguished physicist expressed, but no doubt will be entertained concerning the clearness and ability with which those views have been uttered, or of the influence they have had on French thought. Ever since the time that Laplace in a few pregnant sentences sketched the plan on which the solar system might have been constructed, the subject has been a favourite speculation among French physicists. M. Faye has not been able to resist the temptation to attack this subject, and though, like all attempts at universe construction, the scheme of M. Faye fails to meet all the difficulties which beset the problem, yet it is a most suggestive contribution to the subject, and should prove an incentive to further inquiry. In some respects this cosmogonic theory contrasts very favourably with that of Laplace, and in others, as was natural, it falls behind that of his great predecessor ; but this is

not the place to enter into any details or criticisms of the argument developed. In recalling, however, the services which M. Faye rendered, one would not willingly forget this finished essay ("Sur l'Origine du Monde"), in which is given, with much that is suggestive, a lucid explanation of the state of our knowledge of the solar and stellar systems.

Similarly, it would be out of place to discuss here the views he expressed on the constitution of the sun, the causes of sun-spots, the behaviour of solar prominences or the chemistry of the sun generally. All these are subjects that fell under Faye's notice and which he treated broadly and philosophically, but necessarily without the facts and knowledge that later observations have brought to light. In cosmical physics and chemistry he was to a great extent a pioneer, and if his theories are in some cases for this reason insufficiently supported by exact observation, they are generally characterised by a breadth of view and thoroughness of conception that contrasts favourably with contemporary opinion. In the discussion of problems connected with cosmical meteorology, or with the motions of our own atmosphere, he was, perhaps not so happy, and his writings on cyclonic motions, the laws of storms, the behaviour of tornadoes, and the exceptional phenomena which we occasionally experience will probably be soon forgotten. Not so, however, with such works as the "Cours d'Astronomie nautique" and other mathematical books with which he has enriched French literature, and which are models of arrangement and of clearness of expression.

One could with difficulty recall the numerous services which M. Faye rendered to his Government or the acknowledgments that he received from foreign scientific bodies. He was, of course, Membre de l'Institut and besides a seat at the Bureau des Longitudes which he had occupied since 1862, in succession to Biot, he was called by Marshal MacMahon to fill in his Cabinet the office of Minister of Instruction, at a time when it was thought not impossible that M. Faye might have become Director of the Paris Observatory in succession to Le Verrier. He was elected a Foreign Associate of the Royal Astronomical Society so long ago as 1848, while Belgium, Venice, the United States of America enrolled him among the members of their scientific societies. Full of years and distinction he is removed from us, and with him another link that connects the science of to-day with the science of the past.

W. E. P.

NOTES.

THE new botanical laboratories of the Chelsea Physic Garden are to be opened by Earl Cadogan at a garden party there on Friday, July 25.

A REUTER telegram from Kronstadt in yesterday's *Times* reports that on July 14 the Italian cruiser *Carlo Alberto* received, for the first time, messages by wireless telegraphy from the Poldhu station in Cornwall. These are the first experiments in wireless telegraphy over a distance of 1600 English miles in a straight line by land, and the results are said to have been most successful, the messages received having been very distinct.

AMONG the Civil List Pensions announced in a Parliamentary Paper just issued are the following:—Mr. W. H. Hudson, in recognition of the originality of his writings on natural history, 150*l.*; the Rev. Dr. John Kerr, F.R.S., in recognition of his valuable discoveries in physical science, 100*l.*; Mrs. S. C. Jones, in recognition of the services rendered by her late husband, Principal John Viriamu Jones, to the cause of higher education in Wales, 75*l.*; and Mr. H. Ling Roth in consideration of his services to anthropology, 70*l.*
