

eminent scientists who refuse to accept evolutionary theory and rely instead on more metaphysical alternatives. Scientific findings do not alter human belief so readily.

Huxley says that it is a characteristic of research that its outcome is not known in advance. That is so: but it is a presupposition of outcome that often motivates research, which may bias its interpretation, and which makes it possible that results will not alter preconceptions. In the correspondence for the same issue in which Huxley's reply to *Nature's* earlier editorial on his address appears (29 September, page 366), C. J. Robbins subscribes to the widely-held view that science sets out to falsify theories through experimentation. As the pages of *Nature* show, this is rarely true; the commonest motivation in research might well be exactly the converse.

The concept of IQ itself is a simplistic parameter which assumes that cognitive, perceptual, deductive and mathematical abilities go hand in hand, whereas our selection of individuals (for employment, etc.) shows this cannot be the case. We accept that brilliant mathematicians may be absent-minded, that musicians may be hopeless fine artists, scientists poor communicators. Why then do we hear so little about what we might call intelligence type? Until we have evolved realistic codes of criteria for assessment that reconcile mental measurements with the realities of life I believe we should postpone spurious research into racially-determined IQ, and recognise it as being ill-founded and premature.

In my view this is the most objective manner in which one could admit the limitations of contemporary science, and the irrelevance of research findings to those determined to subscribe to their own beliefs; these two are topics that are ripe for research.

Yours faithfully,

BRIAN J. FORD

Soviet genetics

SIR,—As far as I know, gerontologists have been wary, over the years, of passing opinions on human genetics and on human genetics programmes. I was therefore very interested to read the review by Dr Zhores Medvedev, a noted gerontologist, on the development of human genetics in the USSR since Lysenko ('Soviet genetics: new controversy', 28 July, page 285).

The review bears a title which is frightening for anyone knowing the history of genetics in that country. A new controversy is hardly needed at this stage. The international congress of genetics is due this year in Moscow

and even calling attention to controversy might cause unpredictable side effects. Fortunately, renewed anxiety for the fate of human genetics in the USSR seems premature at this stage; the review gives a brief account of the re-emergence of the discipline, and for the rest is an all-out attack on the retiring director of the Institute of General Genetics of the Academy of Sciences, Dr N. Dubinin.

Of those who reinstated human genetics in the USSR Medvedev writes: "all of them were void of real practical knowledge of human or medical genetics", and one is left to wonder how they happened to have the courage to do it. Furthermore, if those who only had knowledge of drosophila genetics, of radiation, rodents, cytology and theoretical human genetics can be criticised for their contribution what can a gerontologist say about human genetics; in what position is he to pass value judgements?

Dr Medvedev, although he does not say so, must have participated in the discussions, since he says they were peaceful, albeit not very productive. Again one wonders how the new Institute of Medical Genetics was established as an outcome of such a lack of productivity.

One cannot help noticing the amount of negative emphasis put by Dr Medvedev on an action which tended to reconstruct human genetics. It is my opinion that, since these negative emphases diminish the whole operation, he should produce the evidence on which they are based. What, for example, is the evidence that D. K. Beliaev had been appointed in 1976 president of the 1978 Congress? This is puzzling, because Beliaev is general secretary, and Tsitsin (wheat hybrids at Lysenko's time) is president.

The part of the review which is devoted to Dubinin is less important. Dubinin, as others, went through the bitter years of the Soviet geneticists and survived. At present, he seems to have developed his own personal views on the inheritance of human abilities; these views are questionable but since they have been publicly castigated, they are not official views which might endanger those not sharing them. It seems arbitrary to associate them with a controversy which might harm human genetics; he is entitled to his opinions, no less than Medvedev to his own and I to mine. So far as some of Dubinin's work on human genetics is concerned, and so far as I can read, he has recently used erroneous techniques in the study of multivariation in quantitative traits in man. However, it might well be that, as director, he signs work from his institute which might be beyond the capacity of his technical

judgment (for example *Dokl. Akad. Nauk.* **230**, 4: 957-960, 1976).

I believe that the most contradictory aspect of Medvedev's review is that Dubinin is turning against the programme he helped to start a short time ago. I believe that the accusation Medvedev makes, that "Dubinin is working hard to suppress by all possible means the development of genuine research in the field of human genetics in the USSR", and which amounts to public condemnation, is so important, that Medvedev is bound to produce evidence for it. It would be sad for those who have helped in the reconstruction, even for those who have given a minimal contribution, if attempts to create new conflicts hinder development. Human genetics is a hot science to handle: it seems useless to make it even hotter. After all, state and interstate budgets for human genetics can be cut easily, both east and west of Greenwich.

The Messinian salinity crisis

SIR,—Lines in reply to an anonymous critic (20 October, page 646)

When composing lyric verse

Be it critical or worse

It is wise to be quite certain of one's ground,

And not to call absurd

Quite a harmless little word

Lest its meaning be not simple but profound.

Crises evaporitic

Irritate our nameless critic

Rightly so, had we but meant what he implied,

But salinity increased

Until crisis point was reached

Whereupon the fauna disappeared or died.

Oh, 'tis pity I declare

That whatever we prepare

And however clear the message that we send,

There are always colleagues who

Having little else to do

Criticise us when they do not comprehend.

N.B.—The term 'Salinity Crisis' was, I believe, coined by Ruggieri (Systematics Association Publication No. 7 (eds Adams, C. G. and Ager, D. V.), 283-290 (London, 1967)) and referred to the apparent extinction of the marine faunas of the western Mediterranean in Messinian times.

Your faithfully,

C. G. ADAMS
