

toll."

The leading Soviet seismologist also calls into question the expediency of building nuclear power stations in earthquake-prone regions, even if their design is technologically up to standard. The Armenian nuclear power station designed to withstand tremors of up to 8 points did not suffer in the earthquake, but there was a real risk of damage.

One striking feature of last week's catastrophe is that the Soviet press has been full of information about the disaster. This, a consequence of the leadership's policy of *glasnost*, is in sharp contrast with the reticence following the disasters in Ashkhabad in 1948 and Tashkent in 1966. One of the side benefits has been that the relief effort has assumed unprecedented proportions.

Meanwhile, the earthquake has made people forget their differences and join forces in grief, compassion and assistance.

Vladimir Markov
Novosti

Vera Rich writes: Markov is certainly correct to describe the handling of the Armenian earthquake as a telling example of how far Soviet *glasnost* has progressed, even since the Chernobyl disaster of April 1986. Then it was more than 60 hours before an official announcement was made and, even then, the accident was treated as a minor news item. Last week, however, the leading Soviet papers carried at least a brief report in the first available edition, and reversed a long-standing Soviet tradition by carrying disaster coverage on the first page.

The Soviet press also reports that the bureau of the Central Committee of the Communist Party of Armenia was in session when the earthquake struck. The first reaction of the bureau members was to telephone to the Armenian nuclear power station at Medzamor, some 35 km from Yerevan, as well as to the major chemical enterprises in Armenia.

But so far it has not been remarked that both the nuclear power station and the chemical plants have been during the past three years the subject of an environmental campaign backed by several members of the Armenian Academy of Sciences, which particularly criticized the siting off such establishments in a seismic zone. A few weeks ago, in response to this pressure, it was promised that the Medzamor power station would be phased out by 1991, the earliest date by which alternative energy supplies could be ensured.

Similar concerns have more recently arisen in Tadjikistan, the earthquake-prone mountainous republic further east, where it is claimed that hydroelectric dams have been built using safety factors worked out for single dams in low-lying aseismic areas. □

Conflicting views on extent of earthquake threat to Tokyo

Tokyo

A REPETITION of the Great Kanto Earthquake of 1923 would result in widespread death and destruction in the Tokyo area, according to a report released last week by the National Land Agency. The report has shocked Tokyo residents, but critics say it fails to gauge the full possible extent of the disaster.

Tokyo lies in one of the most earthquake-prone regions of the world — second in the list of fast-growing cities 'at risk', on page 626 of this issue. To the east, the Pacific plate plunges beneath Japan and to the south-west the subducting Philippine plate slices into the Izu Peninsula between Suruga and Sagami bays. In 1923, the Great Kanto earthquake, which was centred in Sagami Bay and registered 7.9 on the Richter scale, destroyed large sections of the city and left nearly 150,000 people dead.

To assess the impact of a similar event, the agency divided Tokyo and surrounding prefectures (Saitama, Kanagawa and Chiba) into a 1- or 2-kilometre grid and modelled the effects of the 1923 earthquake on present-day Tokyo, taking into account conditions in each block of the grid. The results suggest a similar death toll to the 1923 event.

Modern buildings within Tokyo are designed to withstand major earthquakes (see below). But in many parts of the city, old wooden houses can still be found squashed together within inches of each other and conditions are ripe for disastrous fires.

If an earthquake should strike in the middle of the night, the death toll would be limited to 80,000, according to the report. But if it came at lunchtime (as in 1923) or early in the evening in winter when stoves would be lit for cooking or heating, fires could be expected to sweep through parts of the city soon after the earthquake and the number of deaths could reach 150,000, with another 200,000 injured, the report says.

But some critics say the report may underestimate the full extent of the damage that might be caused by a major earthquake. For example, no account is taken of recent reclamation and development projects along Tokyo Bay waterfront and no estimate is made of the possible death toll resulting from panic in the underground railways and shopping malls scattered around modern-day Tokyo.

Although computers have back-up systems to cover such events, some economists fear that a major earthquake in Tokyo could cause panic on the world market.

The National Land Agency report, which also maps out responsibilities for the various government ministries and agencies in the event of such a disaster, has been submitted to the Central Disaster Prevention Council, chaired by Prime Minister Noboru Takeshita, which will propose counter measures.

But the only effective solution would probably be decentralization and drastic changes in the planning and development of the city.

Builders look to 'anti-quake' device

JAPANESE engineers have developed an ingenious way to protect tall buildings from earthquakes. A device placed on the top of the building creates 'anti-quakes' to cancel out the effects of earthquake motion.

Tall buildings in Tokyo and other major Japanese cities are designed to flex and sway during earthquakes. The oscillations absorb the earthquake and protect the building from collapse. But the swaying motions can be a frightening experience for people on the top floors even during comparatively minor earthquakes.

Kajima Corporation, a construction company, plans to bring the swaying to a halt with 'anti-quakes'. Kajima's device consists of huge weights (several tons) on wheels placed on the roof of the building. A computer connected to motion and vibration sensors in the basement and mid-floor of the building command hydraulic actuators to move the weights back and forth very rapidly in such a fashion as to cancel

out the forces of the earthquake.

Kajima researchers say their device can reduce motions up to 75 per cent in earthquakes up to magnitude 4 on the Japanese scale of 7. Magnitude 4 earthquakes cause buildings to shake violently, knocking over ornaments and glasses. The device is also effective in preventing motions induced by strong winds of up to 70 kilometres per hour.

By May next year, Kajima Corporation will install its first commercial anti-quake device in an 11-storey building now being built in Kyobashi, Tokyo. The device, however, does suffer from one potential hazard. If the timing is slightly out, the moving weights will amplify rather than decrease oscillation of the building. But Mitsuo Sakamoto of Kajima's Kobori Research Institute says that the computer software contains a "fail-safe" program that can switch the system off if things get out of control.
