

► in Johannesburg last October sparked a student protest movement, known on social media as the “#FeesMustFall” campaign. The protests spread to other universities, which had also proposed fee increases of 10–12%. The movement successfully squashed the hikes, and protestors are now pressing for free tuition at all South African universities.

Without fee increases, however, universities are facing immediate budget shortfalls, which have forced them to make widespread cuts. Astronomer David Block at the University of the Witwatersrand says that he and his colleagues were told at a faculty meeting last month to save money by cutting their use of water, heat and electricity. Earlier this year, he attempted to recruit a promising postdoctoral researcher, but failed because his department lacked money for new hires. “It really has reached a crisis — we’re under tremendous strain.”

UP IN SMOKE

Projects such as a programme to train vaccinology researchers at various institutions, including the University of the Witwatersrand, have had to find outside funding — a temporary stopgap.

Researchers are also worried about access to infrastructure, ever since protests ahead of municipal elections on 3 August led to campus vandalism. Unrest in January shut down University of Pretoria campuses for weeks, and in February, the Potchefstroom campus of North-West University was closed after students torched administration buildings, including a science centre. In May, arsonists burned down a historic auditorium at the University of Johannesburg.

Researchers and university administrators worry that political violence is becoming a new normal. During some of the worst mayhem, in May, Alta Schutte, director of the hypertension unit of North-West University said, “When I go home every day, I am a bit concerned that when I come back, my office, my lab, my hypertension clinic or my biobank will not be there.”

The protest movement is a response to the nation’s persistent inequality. “An upper-middle-income country like South Africa should widen access to education,” says cardiologist Bongani Mayosi at the University of Cape Town. But the violence and intimidation have gone too far, he says.

Danie Visser, deputy vice-chancellor for research and internationalization at the University of Cape Town, agrees. “We are probably at a critical juncture: if the country is able meaningfully to address the issues that brought about the student protests in the first place, our universities — and therefore also our research — will survive and flourish.” ■

Severe-weather forecasts deteriorate when wireless broadband interferes with satellite transmissions.

METEOROLOGY

Interference puts satellite data at risk

US plan to expand mobile-phone bandwidth raises alarm.

BY ALEXANDRA WITZE

As Hurricane Patricia barreled down on Mexico last October, forecasters at the US National Oceanic and Atmospheric Administration (NOAA) grabbed as many satellite images as they could to track its progress. But at least one crucial shot failed to download. A 22 October image from the Geostationary Operational Environmental Satellite (GOES) system showed a black swathe — no data — across most of the Pacific Ocean.

“You couldn’t even see the hurricane,” says Al Wissman, chief of data management and continuity operations for NOAA’s satellite and information service in Silver Spring, Maryland. “That’s how devastated the imagery was.”

The culprit was radio interference from mobile-phone companies. And the problem may soon get worse. The US Federal Communications Commission (FCC) is considering whether to allow a satellite-communications company to share a crucial, additional set of frequencies that NOAA uses for time-critical weather transmissions.

If the application is granted, Ligado Networks of Reston, Virginia, will begin transmitting at frequencies between 1,675 and 1,680 megahertz. That overlaps with the communications range of NOAA’s next

generation of GOES satellites, starting with the game-changing GOES-R probe that is set to launch in November. The satellite will transmit in three times the number of channels as do current satellites, providing images with four times the current resolution, and it will scan for weather events five times faster.

Last month, emergency managers, pilots, private weather forecasters and other groups flooded the FCC with letters arguing against the change. Researchers will discuss the proposal at a meeting of the American Meteorological Society (AMS) in Tuscaloosa, Alabama, on 21 July.

Wireless broadband has been a boon for meteorologists, who can now send crucial tornado, hurricane and other alerts directly to people’s smartphones. “But it can’t come at the risk of interrupting important weather communications that are used in order to be able to deliver the most accurate and reliable forecast,” says Jonathan Porter, vice-president of innovation and development at the private forecasting company AccuWeather in State College, Pennsylvania. Porter also chairs an AMS committee on spectrum allocation.

In general, the US government sets aside swathes of radio frequencies for purposes that protect safety and national security, such as weather forecasting. But in 2010, President Barack Obama told the various agencies

RICKY CARIOTI/WASHINGTON POST

that regulate spectrum-sharing to free up 500 MHz for wireless broadband use by 2020. In November 2012, a company that later evolved into Ligado filed a request to share the 1,675–1,680-MHz band.

Commercial mobile-phone companies are already transmitting at slightly lower frequencies, the 1,670–1,675-MHz band — a situation that has caused problems with NOAA data.

In a representative sample of GOES imagery taken between May and September 2015, the agency found that 3.6% of the data during that stream had been subject to interference. And in May of this year, NOAA clocked 30 events in which satellite transmissions had dropped out, either streaking or nearly obliterating the images. “We consider that to be unacceptable,” Wissman says.

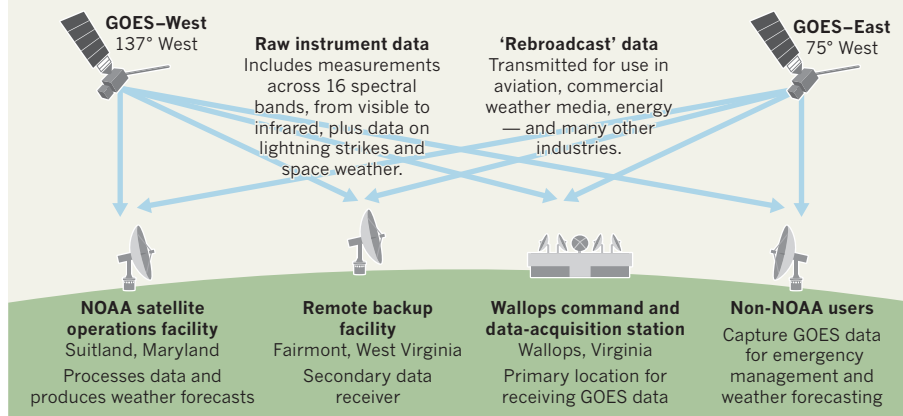

In response, NOAA has begun to shift the transmission frequencies for the radiosonde balloons it launches to obtain vertical profiles of the atmosphere. It also redesigned an aspect of its GOES-R transmissions to be centred on 1,686.6 MHz, in the hope that this would be high enough to escape the interference.

But that change affects only how GOES-R relays its own imagery to Earth. GOES-R has a second job as a sort of internet in the sky, relaying data from 27,000 ground stations including stream gauges, tsunami buoys and seismic stations (see ‘Weather watchers’). If Ligado’s application is granted, that ‘rebroadcast’ service is likely to be interrupted — affecting forecasts of phenomena such as the spread of smoke during wildfires or the disruption of plane flights by volcanic ash.

“It’s just an untenable situation to have in a critical situation,” says William Mahoney, an atmospheric scientist at the National Center for Atmospheric Research in Boulder,

WEATHER WATCHERS

The US government’s Geostationary Operational Environmental Satellite (GOES) system monitors atmospheric and surface conditions in the continental United States — collecting data that power the country’s weather forecasts.

Colorado, and head of the AMS commission on the weather, water and climate enterprise.

One of GOES-R’s big advantages is that it will send updated data as often as every 30 seconds. That’s much more frequent than the 10–30-minute refresh time of the current GOES series, so any disruption to the real-time data flow will be much worse, Porter says.

Ligado has proposed ways to address the concerns, such as establishing blackout zones around NOAA’s receiving stations or creating a cloud-based computing network to handle data distribution for non-NOAA users.

But many of those who have commented publicly are sceptical about such plans. The World Meteorological Organization pointed out that cloud computing is vulnerable when weather data are most needed: during severe storms.

The FCC is accepting replies to the original set of public comments until 21 July. After that, it will grind slowly towards a decision.

In Tuscaloosa next week, meteorologists will sit down for a public discussion with representatives from Ligado about the best way forward. Porter, who will chair the panel, hopes that the government will proceed slowly — perhaps by delaying the bandwidth-sharing or at least phasing it in slowly and documenting any interference.

“This is not just, ‘Oh, a few weather forecasts,’” says Renee Leduc Clarke, a consultant with Narayan Strategy in Washington DC who has been working with clients on the spectrum-sharing issue. “This is equal to lives and property inside our economy — the same economy we’re trying to boost with wireless broadband.” ■

NEUROSCIENCE

Brain-data gold mine released

Massive survey of mouse visual-cortex activity aims to reveal brain’s computational rules.

BY HELEN SHEN

Inspired by the large-scale sky surveys with which astronomers explore the cosmos, neuroscientists in Seattle, Washington, have spent four years systematically surveying the neural activity of the mouse visual cortex. The Allen Brain Observatory’s first data release, on 13 July, provides a publicly accessible data set of unprecedented size and scope, designed to help scientists to model and understand the human brain.

The project is part of an ambitious ten-year brain-research plan announced in 2012 by the

Allen Institute for Brain Science. Designed to catalogue neurons and their electrical characteristics in minute detail, the initiative aims to enable new insights into how perception and cognition arise.

To compile the brain observatory’s first data set, researchers used a specialized microscope to record calcium waves that occur when neurons fire, sampling activity in 25 mice over 360 experimental sessions, while the animals viewed a battery of visual stimuli such as moving patterns of lines, images of natural scenes and short movies. The data set so far includes 18,000 cells in 4 areas of the visual cortex,

making it one of the largest and most comprehensive of its kind. The set also includes information about each neuron’s location and its expression of certain genetic markers. At 30 terabytes, the raw data are too large to share easily, but users can download a more manageable processed data set, or explore it online.

“It’s amazing,” says Anne Churchland, a neuroscientist at Cold Spring Harbor Laboratory in New York. “There’s no other effort I know of where people have looked at so many brain areas with so many stimuli — and importantly, where the data are freely available as well.” ▶

CORRECTION

The article 'Interference puts satellite data at risk' (*Nature* **535**, 208–209; 2016) wrongly stated that William Mahoney would lead a panel on spectrum-sharing at an American Meteorological Society meeting later this month. Jonathan Porter is the panel chairman. In addition, it did not make it clear that Ligado Networks is a satellite-communications company.
