### ABSTRACT

Polar auxin transport plays a divergent role in plant growth and developmental processes including root and embryo development, vascular pattern formation and cell elongation. Recently isolated Arabidopsis pin gene family was believed to encode a component of auxin efflux carrier (Gälweiler et al, 1998). Based on the Arabidopsis pin1 sequence we have isolated a *Brassica juncea* cDNA (designated Bjp<sub>in</sub>1), which encoded a 70-kDa putative auxin efflux carrier. Deduced Bjp<sub>in</sub>1 shared 65% identities at protein level with AtPIN1 and was highly homologous to other putative PIN proteins of Arabidopsis (with highest homology to AtPIN3). Hydrophobic analysis showed similar structures between Bjp<sub>in</sub>1 and AtPIN proteins. Presence of 6 exons (varying in size between 65 bp and 1229 bp) and 5 introns (sizes between 89 bp and 463 bp) in the genomic fragment was revealed by comparing the genomic and cDNA sequences. Northern blot analysis indicated that *Bjp<sub>in</sub>1* was expressed in most of the tissues tested, with a relatively higher level of transcript in flowers and a lower level in root tissues. Promoter-reporter gene fusion studies further revealed the expression of *Bjp<sub>in</sub>1* in the mature pollen grains, young seeds, root tip, leaf vascular tissue and trace bundle, stem epidermis, cortex and vascular cells. Bjp<sub>in</sub>1 was localized on the plasma membrane as demonstrated through fusion expression of green fluorescent protein (GFP). Auxin efflux carrier activity was elevated in transgenic Arabidopsis expressing Bjp<sub>in</sub>1.

**Key words:** *efflux carrier, Brassica juncea, polar auxin transport.*

---

### INTRODUCTION

Charles Darwin had proposed the concept of translocated chemical messengers in higher plants,

which finally resulted in the discovery of polar auxin transport in the 1930s[1],[2]. Studies, including the application of polar auxin transport inhibitors such as TIBA (2, 3, 5-triiodobenzoic acid), have indicated that polar auxin transport plays divergent roles in plant growth and development including apical dominance, tropic growth[3], cell elongation, and lateral root development[4],[5]. Polar auxin transport was also shown to be critical for plant morphogenesis, including leaf vein pattern[6],[7], gynoecium morphogenesis[8], establishment of bilateral symmetry during embryogenesis[9-11], embryo axis formation[12],[13] and etc (for review see

\*\*The nucleotide sequences reported in this paper have been submitted to the GenBank™/EMBL Data Bank with accession numbers AJ132363 (*Bjp<sub>in</sub>1* cDNA), AJ307883 (promoter region of *Bjp<sub>in</sub>1*) and AJ307884 (genomic sequence of *Bjp<sub>in</sub>1*).  
Received May-13-2002 Revised July-22-2002 Accepted July-25-2002

[14]). Polar auxin transport is an energy-requiring, cell-to-cell process that is specific for indole-3-acetic acid (IAA) and synthetic auxin. The current model of polar auxin transport, chemiosmotic hypothesis, which was independently proposed by Rubery and Sheldrade (1974)[15] and Raven (1975)[16], posited that polar auxin transport occurs through the action of cellular auxin influx and efflux carriers located in the plasma membrane of transporting cells. It is the basal location of the efflux carrier that is responsible for the polar nature of auxin transport. Jacobs and Gilbert (1983)[17] used an immunological approach to demonstrate the basal localization of a putative efflux carrier, which provided the support of the later aspect of the model.

The first molecular support of the model came from the characterization of a candidate auxin influx carrier, AUX1 (auxin resistant1, the *Arabidopsis* aux1 mutant showed auxin-resistant root growth phenotype and abolished root gravitropic curvature). AUX1 is a presumptive membrane protein similar to amino acid permeases [18] and was specifically expressed in the root. Further proof of AUX1 as an auxin influx carrier was provided by the work of Yamamoto and Yamamoto (1998)[19]. A breakthrough in the study of polar auxin transport has been marked with the cloning of two genes, *Atpin1* and *Atpin2*, which encoded presumptive auxin efflux carriers[20-24]. Pin-formed inflorescence and decreased polar auxin transport activity of the *Arabidopsis* *pin1* mutant indicated that the primary function of the AtPIN1 protein was for polar auxin transport in the inflorescence axis[25]. The *Atpin1* gene, isolated through En-tagging method, was found to encode a protein with similarity to bacterial and eukaryotic carrier proteins. AtPIN1 protein was detected at the basal end of auxin transport-competent cells in vascular tissues [21]. These studies strongly suggested that AtPIN1 might act as a transmembrane component of the auxin efflux carrier and play a role in auxin transport from shoot apex to root tissue in stems.

While *Atpin1* was found to be widely expressed in all the tissues tested, another member of the pin gene family, *Atpin2*, showed specific expression in the epidermis and cortex of root, with a similar basal location of the protein in the transport-competent cells[23]. Thus, the AtPIN2 together with the AUX1

may act as the component of auxin efflux and influx carrier respectively and take part in the auxin transport from the tip to the base of the root (the basipetal stream), which was required for the root gravitropic. The most compelling evidence of AtPIN2 as a component of auxin efflux carrier came from the experiments with AtPIN2-expressing yeast cells which were resistant to toxic fluoroindoles, an IAA analogy[22], and released preloaded IAA more rapidly than control cells, suggesting that AtPIN2 transports IAA out of the yeast cells[20].

To date several genes encoding auxin efflux carriers, *Atpin1*[1][21], *Atpin2/eir 1*[22],[23], and *Atpin4*[26], have been isolated and some genes encoding PIN-like proteins were detected from *Arabidopsis* genome. We are interested in the function of auxin and polar auxin transport on plant development. Here we report the cloning, expression pattern analysis and functional characterization of a pin-like gene, *Bjpin1*, from *Brassica juncea* through molecular technique and transgenic approaches in *Arabidopsis*.

## MATERIALS AND METHODS

### *Materials*

Enzymes used for DNA restriction and modification were obtained from Boehringer (Mannheim, Germany). DNA primers for polymerase chain reaction (PCR) and "LAPCR in vitro cloning kit" were obtained from TaKaRa Biotechnology (Dalian, China). T<sub>3</sub> and T<sub>7</sub> mMESSAGE mMACHINE™ Kits were obtained from Ambion. Dig-RNA labeling mix, Anti-Pig, were obtained from ROCHE. Western Blue were obtained from Promega. Radiochemicals [ $\alpha$ -<sup>32</sup>P]dCTP and [<sup>14</sup>C]IAA were obtained from Yahui Company (Beijing, China) and SIGMA (St.Louis, USA) respectively. The leaf1 ZAPII cDNA library and genomic library of *Brassica juncea* were kindly provided by Eng-Chong Pua (National University of Singapore).

### *Bacteria and plants*

*Escherichia coli* strain XL-1 Blue (Stratagene, La Jolla, USA) was used for library screening and DNA cloning procedures. *Agrobacterium* strain LBA4404 and GV3101 were used for leaf disc transformation of *Nicotiana tabacum* cv Gx-1 and floral dip transformation of *Arabidopsis thaliana* C24[27, 28]. *Brassica juncea* and tobacco plants were grown in the green house with a 12 h light (26°C) and 12 h dark (20°C) period. *Arabidopsis* plants were grown in a phytotron in soil with a 16 h light (22°C) and 8 h dark (15°C) period.

### *Isolation of the Bjpin1 cDNA and sequence analysis*

DNA manipulation was performed using standard protocols

[29]. The nucleotide sequence of Atpin1[21] and two other Atpin1 homologous sequences (Accession Nos. AC002311, gene T26J12.14, and AC002291, gene F22K20.18, found through searching the GenBank using Atpin1 as bait) were used for designing two reverse degenerated primers pinA1, 5'-AG(A/T/C/G)GG(A/G/T)AT(A/T/- C/G)CCCAT(A/T/C/G)AC-3' and pinA2, 5'-(A/G)TACCA-(A/G/T)AT(A/G/T)AT(A/G)CA(C/T)TG-3', corresponding to amino acid VMGIPL and QCIWY at the position of 115-120 and 140-145 of AtPIN1, respectively. Primers, pinA2 and standard T3, were used for amplification of pin-homologous DNA fragments from the cDNA library of *B. juncea*. PCR products of about 550bp were subcloned into TA vector and clones were further confirmed by PCR using primers pinA1 and T3. Positive clones were then sequenced. Based on the sequences obtained, specific primers pinS1 (5'-TACGTCGCTATGATCCTCGC-3') and pinA4 (5'-CGACGACCTGGACCATGAG-3') were then synthesized for isolation of full-length cDNA from library through PCR-based screening[30]. Plaque-purified phage clones were converted to pBluescript SK derivative using helper phage Exassist according to supplier's (Stratagene) instructions. The clone pBjpin1, which contained the longest cDNA insert, was used for further analyses.

DNA sequencing was performed by TaKaRa Biotechnology (Dalian, China). Computational analysis was performed with the help of the programs of the Wisconsin Genetics Computer Group (GCG Package, Version 10.1). The BLAST search programs were used for sequence comparisons on DNA and amino acid sequences in GenBank, EMBL, dbEST and SwissProt databases. Sequence alignments were performed using the BESTFIT and PILEUP programs. Hydrophobic analysis was performed with PEPLOT program.

### Isolation of genomic sequence of *Bjpin1*

Based on the promoter region of *Bjpin1* (see below), specific primers *Bjpin103* (5' -TTGACCCAATACACTGTATGG-3' ) and *Bjpin1S* (5' -CTTCTTTCTGGTTGATTAGAGAG-3' ) were designed for isolation of *Bjpin1* genomic sequences from *B. juncea* genomic library through PCR-based screening. *Bjpin1* genomic sequence was amplified with *Bjpin103* and standard T<sub>3</sub> primers using obtained positive clone as template, and the resulted PCR fragment, which was around 6 Kb, was subcloned into TA vector and sequenced. Sequence alignments were performed using the BESTFIT programs.

### Northern blot analysis

Materials were harvested from well-watered *B. juncea* plants. RNA was prepared according to the protocol of Logemann et al. (1987)[31]. RNA (20  $\mu$ g per lane) was electrophoretically separated in denaturing 15%(v/v) formaldehyde, 1.5% (w/v) agarose gels and blotted onto Hybond-N+ membranes (Amersham, USA). RNA was fixed onto the membrane by heating for 2 h at 80°C. A 400-bp PCR product of the *Bjpin1* (encoded the amino acid residues at position 305-442) was served as [ $\alpha$ -<sup>32</sup>P]dCTP-labeled hybridization probe. Membranes were hybridized at 65°C in 250 mM sodium phosphate buffer (pH 7.2) containing 7% SDS, 1%

BSA, and 1mM EDTA. Washes were performed at 65 °C in 2×SSC, 0.5% SDS for 15 min and in 0.2×SSC, 0.5% SDS for 20 min[32]. Blots were exposed to Fuji X- films between intensifying screens for 4-5 d at -70°C.

### Isolation of the *Bjpin1* promoter fragment, tobacco transformation and GUS activity assay

"PCR-based DNA walking" technique was employed for isolation of *Bjpin1* promoter region. Genomic DNA of *B. juncea*, digested with Hind III, was ligated to the corresponding adaptor according to the supplier's (TaKaRa, Dalian) instructions. Specific primers *BjPS1* (5' -TACAGAGCCGTAGGCGAGGATCATAG-3' ), *BjPS2* (5' -CGAGGATCATAGCGACGTAGAG-3' ) and *Bjpin1S* (5' -CTTCTTTCTGGTTGATTAGAGAG-3' ) were used for PCR amplification. A 320-bp amplified fragment was subcloned into TA vector and then sequenced to confirm the promoter region of *Bjpin1* gene. Subsequently, the 320-bp DNA fragment of *Bjpin1* promoter region was subcloned into pBI101 binary vector with Hind III/BamH I enzymes. The plasmid, p*Bjpin1*-pro, containing the promoter-uidA coding region, was transformed into *A. tumefaciens* strain LBA4404 for tobacco transformation. Transformation was performed using leaf disc as materials. GUS activity was determined using 5-bromo-4-chloro-3-indolyl  $\beta$ -D-glucuronic acid (X-gluc) as substrate[33].

### In situ hybridization

In situ hybridization of fixed and paraffin embedded flowers of *B. juncea* was performed as described[34]. PCR fragment of *Bjpin1* (position 1041-1451) were ligated into pBSK vector through Sma I cleavage site generating pSKpinV for *Bjpin1*-specific RNA probes. After pSKpinV linearizing BamH I for antisense and Hind III for sense transcription in vitro transcription and digoxigenin labeling were performed, signals were developed with 100  $\mu$ l Western Blue per slide and observed under dark field (Olympus microscope).

### *Bjpin1*-GFP fusion studies

The 2 kb *Bjpin1* coding region (just before the stop codon), which was amplified with primers T3 and G*bjpin1* (5'-GGGGTACCTAACCCGAGTAGAATATAG-3', Kpn I site italic), was cut with Kpn I and Xba I and then ligated to the pre-cut (with same restriction enzymes) binary vector p12G, which contained CaMV35S promoter and GFP (green fluorescent protein) coding region (B Zhang, Shanghai Institute of Plant Physiology, Shanghai). Resulted construct, p12G-*Bjpin1*, was sequenced to confirm that no nucleotide substitutions occurred during the PCR amplification and in frame of the GFP coding region. The p12G-*Bjpin1* was then transformed into *A. tumefaciens* strain LBA4404 for tobacco leaf disc transformation. Resistant tobacco plants were confirmed to be transgenic plants via Northern blot analyses using GFP coding region as hybridization probe.

Roots of transgenic tobacco were transferred onto microscope cover slips and imaged on a fluorescence microscope equipped with a UV lamp and filter (Zeiss GFP filter,  $\lambda_{ex}$ =488nm,  $\lambda_{em}$ =507nm). Plasmolysation of root cell was performed with 20% sucrose solution treatment.

### Assay of IAA transport activity in transgenic *Arabidopsis* inflorescence axes

The 2.6 kb DNA fragment, which was cut with EcoR I from plasmid pBjpin1 and included the full *Bjpin1* gene, was blunted with T4 polymerase. Resulted DNA fragments were then subcloned to the Sma I site of the binary vector pBinAR-kam (from Max-Plank-Institute of Molecular Plant Physiology, Germany) to generate the construct harboring *Bjpin1* in both forward and reverse orientations. Constructs with different orientations were checked with restriction enzymes and then transformed into *A. tumefaciens* strain GV3101. Transgenic *Arabidopsis* plants were obtained using floral dip method and confirmed by PCR using primers spanning the CaMV35S and *Bjpin1* coding region, with genomic DNA as templates.

IAA polar transport activity assay was performed as described by Okada et al. (1991). In short, 2.5 cms of inflorescence axes (at same position in different plants) of transgenic *Arabidopsis* plants were cut and incubated in 1/2 MS[35] solution containing 1.45  $\mu$ M [<sup>14</sup>C]IAA in both normal and inverted orientations for 18 or 24 h. After 2 d [<sup>14</sup>C] radioactivity was measured by liquid scintillation counting (Beckman LS650) with 3 ml counting solutions. Measurement were performed with: 1) 0.5 cm ends of inflorescence axes; 2) both halves (1.25 cm) of inflorescence axes after incubation.

## RESULTS

### Cloning of *Bjpin1* from *B. juncea*

Sequences analyses of a DNA fragment of around 550 bp, amplified from *B. juncea* cDNA library with T3 and degenerated primers revealed that it encoded a peptide sharing 75% identities with AtPIN1 at positions 1 ~ 145, which indicated a putative PIN-like fragment of *B. juncea*. A full-length cDNA, designated as *Bjpin1*, encoding a PIN-like protein was then isolated from *B. juncea*. The *Bjpin1* cDNA has a length of 2557 nucleotides with an open reading

frame present between nucleotides 126 (ATG) and 2042 (TGA). The predicted protein contained 639 amino acid residues and had a molecular mass of ~ 70 kDa, similar to that of previously reported AtPIN1 [21] and AtPIN2/EIR1[22]. The calculated isoelectric point of BjPIN1 was 8.88.

A genomic fragment harbouring the entire *Bjpin1* coding region was isolated through library screening. A comparison between the genomic DNA and cDNA sequences revealed the presence of 6 exons (varying in size between 65 bp and 1229 bp) and 5 introns (sizes between 89 bp and 463 bp) in the genomic fragment (Fig 1A). The complete *Bjpin1* gene had a size of approximately 5 kb, including 5'- and 3'-untranslated regions, and putative 5' regulatory elements.

### Structural organization of the BjPIN1 protein

Fig 1B shows the alignment of BjPIN1, AtPIN1, AtPIN2 and other PIN-like proteins in *Arabidopsis*. BjPIN1 shared high homology with *Arabidopsis* PIN proteins (Tab 1), i.e. 65.1% and 64.4% identities with AtPIN1 and AtPIN2, respectively, and the highest identities (92.7% and 87%, respectively) were found with the putative AtPIN3 and AtPIN7 (accession No. AF087818 and No.AF087820, respectively). Conserved regions were found at N- and C-termini of all the proteins. Hydropathy analysis showed BjPIN1 contained highly hydrophobic domains in both N- and C-terminus of proteins, which are conserved in all PIN and PIN-like proteins (Fig 1B), and a varied central region that is predominantly hydrophilic (Tab 2). Structural analy-

sis indicated the presence of around 11 predicted transmembrane regions in BjPIN1 (Fig 1C), which was similar with AtPIN1.

#### Expression pattern analyses of *Bjpin1*

The cDNA fragment of *Bjpin1* encoding the varied region (amino acid residues position 305 ~ 442)

was used as a hybridization probe to detect *Bjpin1* transcription levels. As shown in Fig 2, a single band of transcripts of approximately 2.5 kb was detected, consistent with the length of the *Bjpin1* cDNA. The Northern blot revealed the presence of *Bjpin1* mRNA in various *B. juncea* tissues, including hypocotyls, cotyledons, leaves, stem, flowers and fruits, with a

#### Fig 2. Northern analysis of *Bjpin1* transcript levels

*Bjpin1* transcript levels were investigated in various tissues of intact *B. juncea* plants grown in soil. Bottom row showed the EtBr staining of RNA. Hy-hypocotyl; Co-cotyledon; Fr-fruit; Fl-flower; St-stem; Ro-root; Le-leaf.

**B.** Alignment of BjPIN1 with other PIN proteins. Numbers on the top indicate amino acid positions. Accession numbers of cDNAs were as follows: AtPIN1, AF089084; AtPIN2, AF086906; AtPIN3, AF087818; AtPIN4, AF087016; AtPIN6, AF087819; AtPIN7, AF087820.

**C.** Hydrophathy analysis of BjPIN1, 11 putative transmembrane regions were marked.

relatively higher and lower level of expression in floral and root tissues.

To further study the expression pattern of *Bjpin1*, a 316-bp promoter region of *Bjpin1* was isolated by “genome walking” and was fused to the *E. coli*  $\beta$ -glucuronidase (*uidA*) coding sequence. The construct was stably integrated into the tobacco genome via *Agrobacterium*-mediated transformation and confirmed via PCR amplification using the primers of CaMV35S promoter and GUS coding gene (Fig 3A). From 10 independent transgenic tobacco lines analyzed, 3 lines showed clear GUS activities in root tip (Fig 3B), leaf vein (Fig 3C), young seeds (Fig 3D), mature anther and pollen grains (Fig 3E) and stem. In stem, GUS activities were detected in epidermis, cortex and vascular cells, and particularly, the leaf trace cells (data not shown). Further in situ hybridization experiment of flowers confirmed the expression of *Bjpin1* in the pollen grains (Fig 3F, sense control not shown).

#### *BjPIN1* was localized on plasma membrane

Based on the chemiosmotic hypothesis, auxin efflux carrier was located on plasma membrane for function of polar auxin transport. To study the cellular localization of *BjPIN1*, the CaMV35S-*Bjpin1*-*gfp* construct resulting in the expression of *Bjpin1*-GFP fusion proteins, was transferred to tobacco plants. Of the 5 resistant tobacco lines, two of them showed high *gfp* mRNA levels according to the Northern blot using *gfp* coding sequence as the hybridization probe (Fig 4A). Image by fluorescence microscopy showed much stronger fluorescence in roots of the transgenic plants (Fig 4B), and the fluorescence was detected only on the surface of cell (Fig 4C) with the polar localization in root tissues (Fig 4D). Root cells of transgenic tobacco were then plasmolysed and fluorescences were found to be restricted to the plasma membrane of plasmolysed cells (Fig 4E, F). Thus the *BjPIN1*-GFP fusion studies suggested *BjPIN1* maybe a plasma membrane protein with the polar localization, which is consistent with its function as an auxin efflux carrier.

#### Polar auxin transport activity in transgenic *Arabidopsis*

To decide whether *Bjpin1* encodes a functional auxin efflux carrier, IAA transport assay was per-

formed on transgenic *Arabidopsis* plants. Both binary vectors harboring forward and reverse orientations of *Bjpin1* under a CaMV35S promoter were used to transform *Arabidopsis*. Measurements of polar auxin transport activity in the inflorescence axes with [<sup>14</sup>C]IAA were performed with either 0.5 cm ends of inflorescence axes or both halves (1.25 cm) of inflorescence axes after incubation (to compare the ratio of [<sup>14</sup>C] in both halves) and the results showed that most of the transgenic plants overexpressing *BjPIN1* possessed an increased auxin transport activities in comparison with control plants. As shown in Tab 3, most of the transgenic plants tested showed increased auxin transport activities, two transgenic lines, T-013 and T-016, had around 2 times higher auxin transport activities than the control. The results, to a certain extent, demonstrated that *BjPIN1* was a functional auxin efflux carrier. However, measurement of inflorescence axes of transgenic plants harbouring antisense orientation of *Bjpin1* did not show decreased polar auxin transport activities.

**Tab 3.** Auxin transport assay of transgenic *Arabidopsis* inflorescence axes (inverse orientation). Assay was performed with 0.5 cm ends of both halves of incubated (18 or 24 h) inflorescence axes. [<sup>14</sup>C] Measurement was done with Beckman LS650. Results were the average of two independent experiments.

Plants	above half/bottom half	T/CK (%)
CK	0.148	100
T-014	0.221	149
T-07	0.212	143
T-013	0.376	254
T-016	0.394	266
T-03	0.158	107
T-05	0.146	99
T-011	0.259	175

## DISCUSSION

Researches on the function, expression pattern and location of recently isolated auxin carriers [18], [21-23], [26] have provided a great wealth of data for understanding the physiological role of auxin and polar auxin transport during plant development. Till now, around 8 different pin-like genes have been found in *Arabidopsis* genome and a few homologous genes from rice as well. Two of the *Arabidopsis* genes,

*Atpin1* and *Atpin2*, have been investigated in detail [21],[23]. Since auxin transport plays divergent roles in plant development, it is possible that some of the pin genes share functional redundancy and every individual member of the PIN family has its distinct functions. It is thought that there are tissue- or even cell-specific auxin efflux carriers that are responsible for multiple auxin transport pathways[36], as indicated by the distinct function of *AtPIN1* and *AtPIN2/EIR1/AGR1* in the shoot and root, respectively[21], [22], and by predominantly lateral localization of *AtPIN3* in endodermal cells[37]. The Arabidopsis mutant *pin1* shows normal tropic responses of shoot and root[25] also indicated that there maybe other pin genes that controlled the lateral auxin transport pathways, according to the Cholodny-Went hypothesis[38]. Models for lateral auxin transport pathway present in shade avoidance have been proposed[39]. There are at least 5 pin-like genes present in *B. juncea* and all of them show different expression patterns [40], which indicates that there is also a pin-gene family in *B. juncea* genome and different members probably play different roles. Distribution of auxin is critical for plant development, especially for plant pattern formation, and auxin efflux carriers are responsible for auxin distribution in plant tissues (cells). Isolation and expression pattern analysis of other pin-like genes will provide informative clues to the role of each PIN protein in plant growth and development.

*BjPIN1* has a similar size (70 kDa) with *AtPIN1* and other PIN-like proteins and share high identities with them (highest identity with *AtPIN3*). They all have similar structural organizations, i.e. conserved, highly hydrophobic domains in both N- and C-terminus and a varied domain present in the central region that is predominantly hydrophilic. However, several genomic sequences, found through database searching, encoding putative PIN-like proteins are relatively unconserved at N- or C- termini. It is still unclear whether these were due to the annotation of genomic structure or the presence of PIN-proteins with different structural organizations.

Northern blots indicated that the *Bjpin1* was expressed in most of the tissues tested with a relatively high level of expression in flowers, however, promoter-GUS fusion studies in transgenic tobacco further revealed the expression of *Bjpin1* in root tips,

stem epidermis, cortex, vascular cells, and particularly the leaf trace cells. This is still unclear as this might due to the short promoter region used or the expression in heterologous plant species. Anyway, the expression pattern of *Bjpin1* was different from that of *Atpin1* that was expressed variety in all tissues, while *Atpin2* was specifically expressed in root tissues. Promoter-GUS fusion studies revealed a strong expression of *Bjpin1* in mature pollen grains, which was consistent with the results of Northern blot analyses, and the pollen expression was further confirmed by in situ hybridization. It is important to note that two pollen-specific cis-elements, "AGAAA" are found in *Bjpin1* promoter region (both putative "TATA" and "CAAT" cassettes were detected). However, a longer promoter region of *Bjpin1* is needed for detailed expression pattern analyses. All these, together with the expression of *Bjpin1* in epidermis and cortex of stem, suggested that *BjPin1* may be involved in flower, particularly pollen grain development, and differential growth in stem through directly auxin transport.

According to chemiosmotic hypothesis[41] it was the basal location of efflux carriers on the plasma membrane of transporting cells that were responsible for the polar nature of auxin transport. This has been confirmed by the polar localization of *AtPIN1* and 2. Here, through GFP fusion studies, we showed *BjPIN1* was a plasma membrane protein, which was consistent with its function as a putative auxin efflux carrier.

Polar auxin transport assay of transgenic Arabidopsis plants with increased level of *BjPIN1* showed higher polar auxin transport activities than control plants. It has been reported that deficiency of *Atpin1* resulted in the decrease of polar auxin transport in the inflorescence axis of Arabidopsis [25]. However, antisense approach of *Bjpin1* in Arabidopsis did not show an obvious decrease of auxin transport in inflorescence axis, this may be due to the relatively low homology of *Bjpin1* to *Atpin1*. To study the physiological role of *Bjpin1* it is necessary to have the transgenic *B. juncea* for detailed analysis.

#### ACKNOWLEDGMENTS

Studies were supported by "the National Natural Science Foundation of China, No. 30070073"

State Key Project of Basic Research, No. G1999011604” and “National Natural Science Foundation of Pan-Deng” We thank Dr. Charles Brearley and Jian Xu for helpful discussions on the manuscript. We greatly thank Dr. Klaus Palme for providing the *Atpin1* nucleotide sequences.
