¹Department of General Surgery, Nanfang Hospital, Southern Medical University, Guangzhou 510515, China; ²School of Biotechnology, Southern Medical University, Guangzhou 510515, China

Aim: To construct a lentivirus-based inhibitor with specific secondary structure that could exert long-term suppression on microRNA-338-3p (miR-338-3p), thus elucidating its molecular function in colorectal carcinoma cells.

Methods: The miR-338-3p inhibitor sequence was synthesized and inserted into pLV-TM plasmid. HEK-293T cells were co-transfected with the lentiviral vectors pLV-TM-miR-338-3p-inhibitor, psPAX2, and pMD2.G. The supernatant containing the lentivirus particles was harvested to determine the viral titer, and then used to infect colorectal carcinoma-derived SW-620 cells. eGFP(+) cells were sorted using flow cytometry. The expression of miR-338-3p in SW-620 cells was determined with real-time RT-PCR, and the expression of the smoothened (SMO) protein was detected using Western blot analysis. The migration ability of the transfected SW-620 cells was assessed with transwell assay.

Results: Restriction endonuclease analysis and DNA sequencing demonstrated that the lentiviral vector pLV-TM-miR-338-3p-inhibitor was successfully constructed. The expression of miR-338-3p in SW-620 cells was significantly decreased by infection with the lentivirus pLV-TM-miR-338-3p-inhibitor. Moreover, the down-regulated expression of miR-338-3p caused up-regulated expression of the SMO protein in SW-620 cells, which showed significantly enhanced migration in transwell assay.

Conclusion: The construction of the lentiviral vector pLV-TM-miR-338-3p-inhibitor with specific secondary structure provides a basis for further studies the molecular function of miR-338-3p in colorectal carcinoma. miR-338-3p may suppress SMO gene expression and thereby inhibit colorectal carcinoma migration.

Introduction

MicroRNAs (miRNAs) are a new class of small, noncoding RNAs (18–25 nt) that regulate the expression of target genes through either translational repression or mRNA cleavage/decay^[1]. miRNAs are known to play important roles in various biological processes, such as development, differentiation and cellular defense responses to infection. These nucleic acids have now been reported to be associated with many types of tumors^[2]. Therefore, analysis of the underlying molecular mechanisms of miRNAs and tumor development is likely to become an important field of research. The development of reagents that can strongly suppress specific miRNAs has also generated much interest and will be important for both basic miRNA research and possible therapeutic strategies.

In recent studies, the majority of the synthetic, low-

molecular weight inhibitors of specific miRNAs are based on anti-miRNA antisense oligonucleotides, in which some or all the ribonucleotides are modified to 2'-O-methylated RNA^[3], locked nucleic acids (LNA) or 2'-methoxyethylated RNA. These modifications provide resistance to cellular nucleases and increase the affinity of these oligonucleotides toward complementary miRNA sequences^[4]. In addition, some antisense oligonucleotides have either flanking sequences or are connected to lipids via linkers^[5, 6]. However, because these reagents are diluted by successive cell divisions and in some cases are metabolized in the cytoplasm, their biological effects are often transient^[7]. As a result, a continuous input of large quantities of dsRNA is required to sustain the down-regulation of miRNAs and RNAi. To achieve the long-term suppression of a specific miRNA, specialized plasmid- and viral-vectors carrying expression units for inhibitory RNA molecules have also been developed, including "antagomir", "eraser" and "sponge"^[8].

miR-338-3p was a recently discovered miRNA and was

found to be involved in cell differentiation. Although miR-338-3p is known to be specifically expressed in neuronal tissue, little is known about its abundance and function during the carcinogenesis of certain cancers^[9]. We constructed a lentiviral vector, pLV-THM-miR-338-3p, and successfully over-expressed this vector in the colorectal carcinoma (CRC)-derived cell line SW-620 in our previous study. This provides the basis for further studies regarding the molecular function of miR-338-3p in CRC. For these studies, we utilized a decoy RNA system that uses a lentivirus-based vector containing RNA expression cassettes to enable the long-term suppression of miR-338-3p. The lentiviral vector is derived from HIV-I and is frequently used to deliver target genes because of its high transduction efficiency and stable integration of the genome into non-dividing cells^[10]. The lentiviral vector is essential for the insertion of the object gene into the cell genome, and the regulatory efficiency of the RNA inhibitor depends on its structural design. Vermeulen *et al*^[11] demonstrated that an miRNA inhibitor containing 8 bp hairpin structures significantly suppressed miR-21 expression in HeLa cells. Furthermore, Haraguchi *et al*^[12] synthesized a series of RNA decoys with stem-loop structures and proved that the 3-nt linkers that are clipped between the miRNA binding sites (MBS) and the stem RNAs result in the strongest inhibitory effects. Therefore, in this study, we will design a miR-338-3p inhibitor that is flanked by sequences that form 8 bp hairpin structures in conjunction with an MBS with a 3-nt linker on both sides. We will design an inhibitor with a combination of these two structures to establish a novel and potent miR-338-3p inhibitor based on a lentiviral vector. Furthermore, this inhibitor should have long-term effects within the cell.

Materials and methods

Design of the miRNA inhibitor sequence

The sequence of the mature miR-338-3p (5'-UCCAGCAU-CAGUGAUUUUGUUG-3') was obtained from miRBase (<http://www.mirbase.org/>). The lentiviral vectors used in this study are pLV-THM, psPAX2 and pMD2.G, which are

a transfer vector, packaging plasmid and envelope plasmid, respectively. The vector information can be found on the Addgene website (<http://www.addgene.org/>). The inhibitor sequence was inserted into the transfer vector between the *Mlu* I and *Cla* I restriction sites according to the Addgene protocol.

The MBS was then flanked by 3-nt linkers, which include an arbitrary sequence and 8 bp hairpin structures. Because the initial sequence of the human gene is located approximately 30 nt downstream of the TATA box^[13], more than 4 bp of arbitrary nucleic acids were required in the 5' flanking region upstream the 5' hairpin structures. This was necessary to construct the vector in accordance with the cloning strategy outlined on the LentiWeb (http://lentiweb.com/cloning_strategies.php). The two restriction sites and their corresponding protective bases were generated at the ends of both the 5' and 3' flanking regions (Figure 1).

To gain a better understand of the secondary structure of the decoy RNA and to determine whether self-annealing could occur inside the MBS sequence, which would result in the decline of its affinity to miR-338-3p, we sent the sequence of our interested gene to the Vienna RNA WebServers (<http://rna.tbi.univie.ac.at/>) for thermodynamic ensemble prediction of our RNA inhibitor (Figure 2).

Transfer vector construction

The third generation of self-inactivating, lentivirus plasmid, pLV-THM (HIV-1-based vector, Addgene, Cambridge, MA, USA), which contains a CMV-driven enhanced green fluorescence protein (eGFP) reporter and an H₁ promoter upstream of the restriction sites (*Mlu* I and *Cla* I) to allow for the introduction of a short-hairpin RNA (shRNA) expression cassette, was used as the transfer plasmid and was linearized by digesting the vector with the restriction enzymes. The miR-338-3p inhibitor oligonucleotides described above were chemically synthesized by Sangon Biotech Co Ltd (Shanghai, China) and were inserted between the *Mlu* I and *Cla* I sites of the pLV-THM plasmid. After the miR-338-3p-inhibitor lentiviral-based

vector was transformed into competent *E. coli* DH5 α cells using the calcium chloride method, antibiotic-resistant colonies were selected on LB-ampicillin agar plates. After colony selection and further propagation, the plasmid was extracted using the alkaline lysis method. The plasmid DNA was then analyzed by restriction enzyme digests and sequence analysis. The plasmid containing the target gene was digested with the restriction enzymes and amplified by PCR. The clones with positive PCR results were subjected to DNA sequencing. After synthesis of the oligonucleotide pairs that code for the decoy RNA that suppresses the endogenous miR-338-3p in cells, we cloned the oligonucleotide pairs between the *Mlu* I and *Cla* I sites of the plasmid, pLV-THM, to generate the RNA inhibitor (Figure 3).

Cell lines and culture

Human embryonic kidney 293T (HEK-293T) cells (Invitrogen, Carlsbad, CA, USA) and the human CRC-derived cell line SW-620 (Shanghai Institutes for Biological Sciences) were cultured in Dulbecco's modified Eagle medium high glucose (H-DMEM) supplemented with 10% heat-inactivated fetal bovine serum (FBS; Hyclone, USA) at 37°C in a humidified incubator with 5% CO₂. The medium was changed every 3 d, and the cells were trypsinized with trypsin/edetic acid when 80%–90% confluence was reached. Cells at passages 4–8 were used for the experiments.

Lentiviral packaging and virus collection

Twenty-four hours prior to transfection, the HEK-293T cells

Figure 3. The sketch of our cloning strategy of the transfer vector.

in logarithmic growth phase were trypsinized, and the cell density was adjusted to 1.0×10^6 cells/mL with complete culture medium. The cells were reseeded into 15-cm cell culture dishes and cultured for 24 h prior to transfection. The cells were 90%–95% confluent on the day of transfection. The recombinant viral vector encoding the miR-338-3p inhibitor and the two packaging plasmids psPAX2 and pMD2.G were extracted with a plasmid extraction kit (Invitrogen,

Carlsbad, CA, USA) and co-transfected into HEK-293T cells according to the manufacturer's instructions. After 8 h of transfection, the cell culture medium was replaced with fresh complete medium. After 24 h of transfection, the expression of eGFP was determined. After 48 h of transfection, the culture medium was collected and centrifuged at $4000\times g$ at 4°C for 10 min to remove any cellular debris. The supernatant was filtered through a $0.45\text{-}\mu\text{m}$ filter into a Plus-20 centrifugal ultrafiltration unit and centrifuged at $4000\times g$ to obtain a high-titer lentivirus stock. The lentivirus without the transgene was used as the negative control and was produced in the same manner as the inhibitor vector.

Virus condensation and titer assay

The high-titer lentivirus was used as the stock virus solution. HEK-293T cells were seeded in 96-well plates (4×10^4 cells/well in a volume of 100 μL) and cultured for 24 h. The medium was removed and 100 μL of the original virus solution and consecutive diluted virus solutions at dilutions of 10^{-1} , 10^{-2} , 10^{-3} , 10^{-4} , and 10^{-5} were added to the cells. After 48 h, 100 μL of complete medium was added to each well and the viral titer was determined by flow cytometry. The viral titer was calculated with the following formula: Titer (293T-transducing units/mL) = $100\,000 \times (\text{target cells}) \times (\% \text{ of eGFP-positive cells}/100) / \text{volume of supernatant in mL}$.

Virus transduction and fluorescent cell selection

SW-620 cells were seeded at 1.0×10^5 cells per well in 24-well plates in DMEM containing 10% FBS. After 24 h incubation, the cells were transduced with each lentivirus stock (3.0×10^5 Titer Unit). The SW-620 cells were then incubated for an additional 48–72 h prior to identifying the eGFP(+) cells by flow cytometry (Becton Dickinson, CA, USA).

Detection of miR-338-3p expression with real-time RT-PCR

Total RNA from SW-620 cells infected with the miR-338-3p expression vector was prepared using the TRIzol reagent (Invitrogen, Carlsbad, CA, USA) after viral transduction. The precipitate was dissolved in DEPC-treated water, and a nucleic acid protein analyzer (Beckman Coulter, USA) was used to determine the RNA concentration. The purity and integrity of the RNA were identified as follows: the $A_{260\text{ nm}}/A_{280\text{ nm}}$ was ≥ 1.8 , and the band ratio of 28S RNA to 18S RNA was ≥ 1.5 in formaldehyde denaturing gel electrophoresis. Accurate quantitation of the mature miR-338-3p was obtained using the TaqMan microRNA Assays (Applied Biosystems, Foster City, CA, USA). Briefly, the reverse transcription reaction was performed using 10 ng of total RNA and the looped primers. Real-time PCR was performed using the standard TaqMan microRNA Assays protocol on the iCycler iQ Real-Time PCR Detection System (Bio-Rad). The PCR reaction (20 μL) included 1.33 μL reverse transcription product, 1 $\times$ TaqMan Universal PCR Master Mix, No AmpErase UNG, 0.2 $\mu\text{mol/L}$ TaqMan probe, 1.5 $\mu\text{mol/L}$ forward primer and 0.7 $\mu\text{mol/L}$ reverse primer. The reactions were incubated in a 96-well plate at 95°C for 10 min followed by 40 cycles of 95°C

for 15 s and 60°C for 1 min. The miR-338-3p expression level was measured using the C_t (threshold cycle) method. The C_t is the fractional cycle number at which the fluorescence of each sample passes the fixed threshold. The $\Delta\Delta C_t$ method for relative quantitation of gene expression was used to determine the miR-338-3p expression levels. The ΔC_t was calculated by subtracting the C_t of U6 from the C_t of the miR-338-3p. The $\Delta\Delta C_t$ was calculated by subtracting the ΔC_t of the reference sample from the ΔC_t of each sample. The fold change was calculated using the equation $2^{-\Delta\Delta C_t[14]}$. The Taqman microRNA Assays for U6 RNA was used to normalize the relative abundance of miR-338-3p. The above experiment was repeated at least three times.

miRNA target prediction

The analysis of miR-338-3p-predicted targets was performed using the algorithms TargetScan (<http://targetscan.org/>), PicTar (<http://pictar.mdc-berlin.de/>) and miRanda (<http://www.microrna.org/microrna/home.do>).

Detection of smoothened (SMO) protein expression by Western blot analysis

SW-620 cells were rinsed twice with cold PBS buffer and were then lysed in ice-cold lysis buffer containing 150 mmol/L NaCl, 50 mmol/L Tris-HCl (pH 7.6), 0.1% SDS, 1% Nonidet P-40, and protease inhibitor cocktail (Boehringer Mannheim, Lewes, UK). The samples were cleared by centrifugation at $13\,000\times g$ for 10 min. The cellular protein (50 μg) was subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and electrotransferred to polyvinylidene fluoride (PVDF) membranes (Immobilon, Bedford, MA, USA). After blocking in 20 mmol/L Tris-HCl, (pH 7.6) containing 150 mmol/L NaCl, 0.1% Tween-20, and 5% non-fat dry milk, the membranes were incubated with primary antibodies against SMO or β -actin, which was used as a sample loading control, overnight at 4°C . The membranes were then incubated with horseradish peroxidase-conjugated secondary antibody. The blot was developed using the ECL detection kit (Amersham Pharmacia Biotech) according to the manufacturer's instructions. This experiment was repeated at least three times.

Transwell migration assay

The migration assay was performed using transwell cell culture chambers (8 $\mu\text{mol/L}$ pore size polycarbonate membrane, Costar). SW-620 cells were resuspended in DMEM with 0.1% FBS at a concentration of 3×10^5 cells/mL. The upper chamber was loaded with 100 μL cell suspension and the lower chamber was loaded with 600 μL DMEM supplemented with 10% FBS. After incubation for 48 h at 37°C in a 5% CO_2 atmosphere, the filter was fixed with 4% paraformaldehyde and stained with crystal violet. The cells on the upper side of the filter were wiped off with a cotton swab. The cells that migrated to the underside of the membrane were counted under a microscope. Ten microscopic fields ($\times 400$) were randomly selected for cell counting. This experiment was repeated at least three times.

Statistical analysis

The relative expression analysis of the target gene was performed using REST-XL (Relative Expression Software Tool, available at <http://www.gene-quantification.info/>). All data in the experiment were presented as the average $\pm$ standard deviation (mean $\pm$ SD). Comparisons between the groups were analyzed with a one-way ANOVA and Student-Newman-Keuls q test using the SPSS 13.0 software (SPSS Inc, Chicago, IL, USA). P values less than 0.05 were considered statistically significant.

Results

Analysis of the miR-338-3p-inhibitor sequence

As shown in Figure 2B, the MBS was unlikely to form a self-annealing sequence, and the other elements were not predicted to block the MBS. Therefore, the structure of the miRNA inhibitor should be completely complementary to the target miRNA sequence.

Packaging of the pLV-TM-miR-338-3p-inhibitor lentivirus and titer assay

HEK-293T cells were co-transfected with the transfer plasmid, pLV-TM-transgene, the packaging plasmid, psPAX2, and the envelope plasmid, pMD2.G. GFP was detected 24 h after co-transfection (Figure 4). Moreover, after 48 h infection with the diluted lentivirus, different levels of eGFP were also expressed in the HEK-293T cells (Figure 5). The viral titer was calculated as the proportion of fluorescent cells that was determined by flow cytometry, and the viral titer was 4.8×10^8 TU/mL.

Virus transduction and fluorescent cell identification

GFP was expressed 48 h after the SW-620 cells were transduced by the lentivirus, and the cells were observed under a fluorescence microscope (Figure 6A–6B). This suggests that the miR-338-3p-inhibitor vector was successfully transduced into the SW-620 cells. The eGFP(+) fluorescent cells were then identified using flow cytometry (Figure 6C–6E).

Real-time RT-PCR for detection of miR-338-3p expression in a CRC-derived cell line

To study the expression pattern of miR-338-3p in SW-620 cells

Figure 4. HEK-293T cells transfected with recombinant plasmid, psPAX2 and pMD2.G. (A) HEK-293T cells under light microscope (20 $\times$); (B) HEK-293T cells under fluorescent microscope (20 $\times$).

after lentivirus transduction, we performed real-time RT-PCR to detect miR-338-3p expression in the SW-620 cells. The real-time RT-PCR results indicated that the miR-338-3p cDNA increased exponentially and then plateaued. The miR-338-3p amplification curve was a typical reverse S pattern (Figure 7A) and showed higher amplification efficiency. The miR-338-3p PCR product was 72 bp long, the corresponding T_m was $84.09 \pm 0.15^\circ\text{C}$, the melting temperature was even, and the shape of the peak was sharp (Figure 7B). As shown in Figure 7C, the expression level of miR-338-3p in the treatment group is less than one third of the expression in the control cells that were not transduced with the inhibitor vector.

Biological functions of miR-338-3p in a CRC-derived cell line

To further investigate the functions of miR-338-3p in CRC cells, we constructed a SW-620 cell line with down-regulated miR-338-3p expression. This SW-620 cell line stably expressed the miR-338-3p inhibitor from the lentivirus vector, pLV-TM-miR-338-3p-inhibitor. Most miRs are hypothesized to control gene expression by base-pairing with the miR-recognizing elements (miR-RE) found in their messenger targets. We utilized all three currently available major prediction programs, TargetScan, miRanda and PicTar, to analyze the potential interactions between miR-338-3p and SMO. At least two of these algorithms (TargetScan and miRanda) reveal a potential miR-338-3p target site in the SMO mRNA 3'-UTR region (Figure 8A).

Figure 5. HEK-293T cells transduced by lentivirus diluted in different density of 10^0 , 10^{-1} , 10^{-2} , 10^{-3} , 10^{-4} , and 10^{-5} . (A) HEK-293T cells under light microscope (20 $\times$); (B) HEK-293T cells under fluorescent microscope (20 $\times$).

Figure 6. SW-620 cells infected by lentivirus (3.0×10^5 TU) before and after flow cytometry selection. (A, B) SW-620 cells infected by lentivirus before flow cytometry selection (A: light microscope; B: fluorescent microscope). (C) SW-620 cells with eGFP(+) were distinguished by flow cytometry. (D, E) SW-620 cells infected by lentivirus after flow cytometry selection (D: light microscope; E: fluorescent microscope).

To determine whether miR-338-3p affects SMO expression in CRC cells, we analyzed the effects of miR-338-3p ectopic expression. We transduced the lentivirus vector, pLV-TM-miR-338-3p-inhibitor, into SW-620 cells and used Western blot

Figure 7. Real-time RT-PCR analysis detecting miR-338-3p expression in SW-620 cells. (A) miR-338-3p cDNA concentrations' Log value as ordinate, C_t value as abscissa. (B) T_m of miR-338-3p was 84.09°C . (C) Expression of miR-338-3p detected by real-time RT-PCR. Expression of U6 snRNA was used as internal control. ^b $P < 0.01$ versus control group.

analysis to determine whether there were changes in the SMO protein level. Introduction of the miR-338-3p-inhibitor caused a significant decrease in the level of miR-338-3p and increased the level of the SMO protein (Figure 8B). This result strongly suggests the post-transcriptional regulation of the SMO protein by miR-338-3p.

To gain a better understanding of changes in the cell phenotype, we used a transwell migration assay to examine the mobility of SW-620 cells transduced with the miR-338-3p-inhibitor. The results of this study demonstrated that a greater number of miR-338-3p-inhibitor-positive cells migrated to the lower side of the membrane than the miR-338-3p-inhibitor-negative cells (Figure 8C–8E).

Discussion

miRNAs play a key role in the regulation of basic biological activities, such as the growth, development, and differentiation of organisms, and because of this, unbalanced miRNA expression may contribute to many human diseases, particularly the

occurrence and development of tumors^[14]. miR-338-3p was a recently discovered miRNA that was found to be involved in cellular differentiation. It was reported that miR-338-3p was a tumor suppressor gene in central nervous system tumors, the expression of which was decreased in central nervous system tumor cell lines. Furthermore, the miR-338-3p sequence is located within intron-8 of the apoptosis-associated tyrosine kinase (AATK) gene, and optimal neurite growth requires not only the enzymatic activity of AATK but also the intronic miR-338-3p generated from the chromosomal AATK gene^[15]. Tsuchiya *et al*^[16] have reported that miR-338-3p contributes to the formation of epithelial basolateral polarity by facilitating the translocation of β 1-integrin to the basolateral membrane, which highlights a potentially important role for miR-338-3p in the process of epithelial cell differentiation. Huang *et al*^[17] demonstrated that a decrease of miR-338-3p expression in hepatocellular carcinoma (HCC), which is another type of epithelial cell-derived cancer, was significantly associated with TNM stage, vascular invasion, intrahepatic metastasis, tumor size and tumor grade. In our previous study, we demonstrated that miR-338-3p expression was down-regulated in both CRC samples and CRC-derived cell lines. We also demonstrated that miR-338-3p was associated with an unfavorable disease-free survival that was independent of clinical factors in specimens from CRC patients treated by both curative surgery and adjuvant chemotherapy (data not shown). To confirm the molecular mechanism of miR-338-3p in CRC, it is necessary to observe the biological effects of the up- and down-regulation of miR-338-3p. We constructed a CRC cell line in which miR-338-3p was over-expressed. This cell line was constructed by transducing the lentivirus vector, pLV-TM-miR-338-3p, into SW-620 cells. However, the long-term suppression of miR-338-3p in CRC cells remains a problem that has yet to be solved.

For the stable expression of genes in target cells, lentivirus-based drugs or gene therapy is a potential therapeutic approach for the treatment of cancers. In recent years, lentiviral vectors have emerged as promising tools for anti-tumor immunotherapy and gene therapy because of their ability to transduce a wide variety of dividing and non-dividing cell types, including tumor cells, dendritic cells and T cells. The modification of cancer cells with various types of miRNAs that have been shown to be involved in tumor development is performed using lentiviral vectors in the majority of relative studies because of efficient transgene delivery that results in either the over-expression or knockdown of miRNAs both *in vitro* and *in vivo*^[18]. These approaches have major implications for the adoptive cellular therapy of virus-associated malignancies and cancer^[19]. In conclusion, the potential of lentiviral vectors as a generally applicable "off-the-shelf" therapeutic for anti-tumor biotherapy should be highlighted.

In this study, we successfully developed a novel lentivirus-based miR-338-3p inhibitor with a hairpin structure. Several previous studies have reported the construction of a RNA decoy with two MBS inside the stem-loop structure^[20]. However, this structure may cause self-annealing between the two MBS when they are transcribed into RNA. This will most likely reduce the inhibitory potential of the RNA decoy^[21]. Modifying the sequences of two MBS to prevent them from being complementary to each other is a sophisticated process. We chose the inhibitory structure of one MBS with two 8 bp hairpins flanking it on both sides and 3-nt linkers connecting the hairpin and MBS. Notably, we show that our RNA decoy can specifically inhibit endogenous miR-338-3p to induce the corresponding biological effect. In our study, we explored the relationship between the expression level of miR-338-3p and the specific biological effects in CRC, such as invasion and metastasis. The success of the miR-338-3p inhibitor is

extremely beneficial for further research.

Recently, SMO, which is the key activator of the Hedgehog (Hh) signaling pathway, was reported to induce CRC invasion and metastasis by targeting the glioma-associated oncogene homologue 1 (GLI-1), a downstream target of the Hh signal^[22]. With the application of bioinformatics prediction programs, such as TargetScan, PicTar and miRanda, we found that miR-338-3p and the 3'-UTR of SMO mRNA had complementary binding sites. From this, we hypothesized that SMO may be a new target of miR-338-3p in CRC; however, this finding has not yet been reported. In this study, the SMO protein was up-regulated in SW-620 cells transduced with pLV-TM-miR-338-3p-inhibitor, and this was confirmed by Western blot analysis. Moreover, decreased expression of miR-338-3p increased the expression of the SMO protein in SW-620 cells, which showed significantly enhanced invasive ability in a transwell assay. Consistent with Huang *et al*^[23], our data indicate that miR-338-3p suppresses SMO gene expression to inhibit CRC migration, which suggests that SMO is a potential anti-tumor candidate for the treatment and prevention of CRC.

Therefore, this tool could be applied to the analysis of regulatory networks that are formed either transiently or stably between miR-338-3p and coding genes. This is also applicable to the construction of a miR-338-3p knockdown mouse. Because the mouse U6 promoter regulated by Cre-loxP has already been well-established, time- and tissue-specific miRNA knockdown in the mouse should be possible using modified lentivirus vector expression systems for further studies regarding the alterations of biological functions in CRC^[24]. Because of these properties, our miR-338-3p inhibitor will be very useful for future studies and may also have potential as a novel human gene therapy. Using recent evidence from pharmaceutical studies focusing on siRNA, our objective is to develop an efficient drug delivery system for a miRNA inhibitor. Furthermore, the reduction in potential side effects of the molecule when the miRNA is transduced by a lentivirus *in vivo*, such as unwanted cytokine responses, remains an additional goal.

Abbreviations

CRC, colorectal carcinoma; miR, microRNA; 3'-UTR, 3'-untranslated region; MBS, miRNA binding site; SMO, smoothened
