Aim: Alpha7-nicotinic acetylcholine receptor ($\alpha 7$ nAChR) is a ligand-gated Ca^{2+} -permeable ion channel implicated in cognition and neuropsychiatric disorders. Activation of $\alpha 7$ nAChR improves learning, memory, and sensory gating in animal models. To identify novel $\alpha 7$ nAChR agonists, we synthesized a series of small molecules and characterized a representative compound, Br-IQ17B, N-[(3R)-1-azabicyclo[2,2,2]oct-3-yl]-5-bromoindolizine-2-carboxamide, which specifically activates $\alpha 7$ nAChR.

Methods: Two-electrode voltage clamp (TEVC) recordings were primarily used for screening in *Xenopus* oocytes expressing human $\alpha 7$ nAChR. Assays, including radioisotope ligand binding, Western blots, whole-cell recordings of hippocampal culture neurons, and spontaneous IPSC recordings of brain slices, were also utilized to evaluate and confirm the specific activation of $\alpha 7$ nAChR by Br-IQ17B.

Results: Br-IQ17B potently activates $\alpha 7$ nAChR with an EC_{50} of $1.8 \pm 0.2 \mu\text{mol/L}$. Br-IQ17B is selective over other subtypes such as $\alpha 4\beta 2$ and $\alpha 3\beta 4$, but it blocks 5-HT_{3A} receptors. Br-IQ17B displaced binding of the $\alpha 7$ blocker [³H]-MLA to hippocampal crude membranes with a K_i of $14.9 \pm 3.2 \text{ nmol/L}$. In hippocampal neurons, Br-IQ17B evoked $\alpha 7$ -like currents that were inhibited by MLA and enhanced in the presence of the $\alpha 7$ PAM PNU-120596. In brain slice recordings, Br-IQ17B enhanced GABAergic synaptic transmission in CA1 neurons. Mechanistically, Br-IQ17B increased ERK1/2 phosphorylation that was MLA-sensitive.

Conclusion: We identified the novel, potent, and selective $\alpha 7$ agonist Br-IQ17B, which enhances synaptic transmission. Br-IQ17B may be a helpful tool to understand new aspects of $\alpha 7$ nAChR function, and it also has potential for being developed as therapy for schizophrenia and cognitive deficits.

Introduction

The nicotinic acetylcholine receptors (nAChRs) are pentameric integral membrane proteins that belong to a superfamily of ligand-gated ion channels including serotonin 5-HT₃ receptor and GABA_A receptor. The nAChRs form non-selective cation channels composed of either homomeric α - or heteromeric α/β subunits^[1]. The specific assembly of nAChR subunits determines the biophysical and pharmacological properties of the channel receptor. For instance, homomeric $\alpha 7$ nAChR is

characterized by its high calcium permeability ($P_{\text{Ca}}:P_{\text{Na}} \approx 10$), its rapid desensitization in the presence of agonists, and its inhibition by the antagonists α -bungarotoxin and methyllycaconitine (MLA)^[2,3].

The $\alpha 7$ nAChR is a homopentameric receptor in the mammalian central nervous system (CNS) with limited peripheral expression, thus reducing potential side effects from inhibition. The $\alpha 7$ nAChR is highly expressed in the brain regions that are critical for cognition, attention processing, and memory formation, particularly in the hippocampus and frontal cortex^[2]. The localization of $\alpha 7$ nAChR is both presynaptic and postsynaptic, and nAChR is involved in numerous processes, including the modulation of neurotransmitter release^[4], the regulation of postsynaptic excitability^[5], and hippocampal

synaptic plasticity^[6].

The disruption of $\alpha 7$ nAChR activity has been implicated in the pathophysiology of neuropsychiatric conditions such as Alzheimer's disease (AD) and schizophrenia. Genetic studies show that the $\alpha 7$ nAChR gene CHRNA7, which is located on chromosome 15q14, is linked with sensory gating deficits in schizophrenic patients^[7]. The analysis for association of promoter variants in the CHRNA7 gene with schizophrenia shows an inhibitory deficit of P50 auditory evoked potential response from schizophrenics and decreased function of transcription from the gene^[8]. In biochemical experiments, the analysis of postmortem tissue reveals a marked reduction of $\alpha 7$ nAChR protein levels in various brain regions of schizophrenics^[9]. In DBA/2 mice, hippocampal $\alpha 7$ nAChR density is closely correlated with sensory gating, and low α -bungarotoxin binding is associated with poor gating^[10]. Knocking out $\alpha 7$ nAChR in mice results in a comparable deficit in sustained attention, a characteristic symptom of schizophrenia, when compared to WT mice^[11]. For AD, the levels of $\alpha 7$ nAChR proteins are decreased in the hippocampus of AD patients^[12]. β -Amyloid peptide₁₋₄₂ ($A\beta_{1-42}$) binds selectively to neuronal $\alpha 7$ nAChR with picomolar affinity in neuritic plaques^[13], leading to the intraneuronal accumulation of $A\beta_{1-42}$ and $\alpha 7$ nAChR complexes^[14], rapid tau phosphorylation^[15], the reversible blocking of the $\alpha 7$ nAChR channel^[16], the disruption of calcium homeostasis, and neuronal cell death^[17], whereas $\alpha 7$ activation confers neuroprotection against $A\beta$ -induced cellular toxicity^[18]. Therefore, a hypothesis has been proposed that the pharmacological activation of $\alpha 7$ nAChR can serve as potential therapy for the treatment of schizophrenia and AD. A number of distinct $\alpha 7$ agonists have been identified and tested in the early phases of clinical trials. Positive phase II clinical data were previously reported with EVP-6124 ((R)-7-chloro-N-quinuclidin-3-yl)benzo[b]thiophene-2-carboxamide and TC-5619 ((2S,3R)-N-[2-(pyridin-3-ylmethyl)-1-azabicyclo[2.2.2]oct-3-yl]benzo[b]furan-2-carboxamide) for improving the symptoms of schizophrenia. When combined with atypical antipsychotic treatment, both EVP-6124 and TC-5619 show beneficial effects on cognition and are generally well tolerated in subjects with stable schizophrenia^[19-21]. However, there are several $\alpha 7$ agonists that have failed in clinical trials due to adverse events related to cardiovascular and gastrointestinal functions, lack of efficacy, or an insufficient therapeutic index^[22-24], thus indicating the need to identify novel chemicals that can selectively activate $\alpha 7$ nAChR.

In this study, we described a novel, selective $\alpha 7$ nAChR partial agonist, Br-IQ17B, (N-[(3R)-1-azabicyclo[2.2.2]oct-3-yl]-5-bromoindolizine-2-carboxamide) identified from indolizine derivatives using electrophysiology as a primary functional screen. With radioisotope binding assays, brain slice recordings, and Western blotting, we confirmed that Br-IQ17B selectively activates $\alpha 7$ nAChR function with high-affinity binding to $\alpha 7$ nAChR and displays weak interactions with non- $\alpha 7$ nAChR subtypes. The Br-IQ17B activity was further confirmed by its activation of $\alpha 7$ nAChR in native neurons and its improvement of synaptic transmissions recorded from hip-

pocampal brain slices. Our findings demonstrate a selective and novel $\alpha 7$ agonist, Br-IQ17B, that activates $\alpha 7$ currents both in hetero-expression system and neurons. Br-IQ17B can be a helpful pharmacological tool in understanding new aspects of $\alpha 7$ nAChR functionality, and it may lead to the development of therapy for neuropsychiatric disorders such as AD and schizophrenia.

Materials and methods

Chemicals

Br-IQ17B was synthesized in the Medicinal Chemistry Laboratory of the State Key Laboratory of Natural and Biomimetic Drugs, Peking University Health Science Center, China. (-)-Nicotine was obtained from Tocris (Ellisville, MS, USA). [³H]-MLA was provided by American Radiolabeled Chemicals (ARC, St Louis, MO, USA). All other compounds were purchased from Sigma (St Louis, MO, USA).

Animals

Sprague-Dawley rats were obtained from Vital River Laboratories Technology Co, Ltd (Beijing, China). The care and use of all animals were performed in accordance with the guidelines for Animal Use and Care of Peking University Health Science Center.

Two-electrode voltage clamp (TEVC) in *Xenopus* oocytes

Oocytes were harvested from *Xenopus laevis* female clawed frogs after anesthesia and washed twice in Ca²⁺-free OR2 solution (82.5 mmol/L NaCl, 2.5 mmol/L KCl, 1 mmol/L MgCl₂, 5 mmol/L HEPES, pH 7.4). Oocytes were transferred to approximately 25 mL tubes and treated with 2 mg/mL collagenase in OR2 solution (Sigma type II, Sigma-Aldrich Inc, St Louis, MO, USA) for 20 min at 20–25 °C with gentle rotation. Stage V or VI oocytes were selected for microinjections.

For two-electrode voltage clamp recordings in oocytes, capped cRNAs were transcribed *in vitro* using the T3 mMES-SAGEmMACHINE Kit (Ambion, Austin, TX, USA) following the linearization of plasmids in pBluescript KSM vectors. The oocytes were injected with 46 nL of cRNA solution containing approximately 20 ng human $\alpha 7$ nAChR cRNA or approximately 1 ng human 5-HT_{3A} cRNA using a microinjector (Drummond Scientific, Broomall, PA, USA). For the expression of heteromeric rat $\alpha 3\beta 4$ and rat $\alpha 4\beta 2$ nAChRs, approximately 2 ng total cRNAs were injected in a 1:1 combination of each subunit. For GABA_A receptors, cRNAs encoding $\alpha 1$, 2-, 3- or 5-, $\beta 3$, and $\gamma 2$ were mixed in a ratio of 1:1:1 and microinjected into oocytes to a total of approximately 1.5 ng. Oocytes were kept at 17 °C in ND96 solution (96 mmol/L NaCl, 2 mmol/L KCl, 1.8 mmol/L CaCl₂, 1 mmol/L MgCl₂, 5 mmol/L HEPES, pH 7.4 adjusted with NaOH).

Recordings were made 2–5 days post-injection. Oocytes were impaled with two microelectrodes (0.5–1.0 M Ω) filled with 3 mol/L KCl in a 40- μ L recording chamber. The membrane potential was held at -90 mV using standard voltage clamp procedures. Currents were recorded in Ringer's solution (115 mmol/L NaCl, 2.5 mmol/L KCl, 10 mmol/L HEPES,

1.8 mmol/L CaCl_2 , 1 mmol/L MgCl_2 , 0.0005 mmol/L atropine) at room temperature ($22 \pm 1^\circ\text{C}$) using a GeneClamp 500B amplifier (Axon Instruments, Union City, CA, USA).

Radioisotope ligand binding assay in crude membranes

Cerebral hippocampi from male Sprague-Dawley rats weighing 230 to 250 g were placed in 0.32 mol/L ice-cold sucrose containing protease inhibitors (Protease Inhibitor Cocktail Tablets; Roche Diagnostics, Indianapolis, IN, USA) (one tablet per 50 mL). For crude membrane preparations, brain tissues were homogenized and centrifuged at $1000 \times g$ at 4°C for 10 min. The supernatant was centrifuged for 10 min at $20000 \times g$ at 4°C , and the pellet was washed twice by centrifugation at $40000 \times g$ for 10 min. Crude membranes were stored at -80°C until use.

The saturation binding for $\alpha 7$ nAChR was performed in a final volume of 500 μL binding buffer (120 mmol/L NaCl, 5 mmol/L KCl, 2 mmol/L CaCl_2 , 2 mmol/L MgCl_2 , and 50 mmol/L Tris-Cl, 0.1% (*w/v*) BSA, pH 7.4, 4°C) containing 200 μg of membrane proteins and different concentrations of the $\alpha 7$ antagonist [^3H]-MLA (100 Ci/mmol ; ranging from 0.03 to 30 nmol/L) in the presence or absence of 30 $\mu\text{mol}/\text{L}$ unlabeled MLA at room temperature for 90 min. The concentration-dependent inhibition of binding was tested by incubating 200 μg of membrane proteins with different concentrations of Br-IQ17B ranging from 3 nmol/L to 3 $\mu\text{mol}/\text{L}$ dissolved in buffer with 5 nmol/L [^3H]-MLA in 500 μL . The nonspecific binding was determined in the presence of 30 $\mu\text{mol}/\text{L}$ MLA. All mixtures were incubated at room temperature for 90 min.

For all experiments, the binding reaction was terminated by vacuum filtration onto Filtermat A filters presoaked with 2% *v/v* BSA for 2 h. Filters were immediately rinsed twice with 4 mL ice-cold reaction buffer, and the PerkinElmer MicroScint-20 scintillation cocktail was added. The bound [^3H]-MLA was measured using a Wallac 1450 MicroBeta TriLux liquid scintillation luminescence counter (PerkinElmer, Waltham, MA, USA).

Western blot analysis

PC12 cells were starved overnight in serum-free medium to reduce basal phosphorylation. After treatment with compounds, reactions were terminated by placing the culture dish on ice and removing the incubation medium by aspiration. Cells were washed twice with D-PBS and treated with ice-cold lysis buffer (150 mmol/L NaCl, 20 mmol/L Tris, 1% Triton X-100, 1% sodium deoxycholate, 0.1% SDS, 10 mmol/L EDTA, pH 8.0), supplemented with protease inhibitor mixtures (Protease Inhibitor Cocktail Tablets; Roche Diagnostics, Indianapolis, IN, USA) on ice for 30 min. Cell lysates were then centrifuged at $13000 \times g$ for 20 min to yield protein extracts in the supernatant.

For Western blots, protein samples were separated on SDS-polyacrylamide gel and transferred electrophoretically onto nitrocellulose membranes (Millipore, Boston, MA, USA). After being blocked with the 5% powdered nonfat milk or 5% BSA in TBS-T (Tris-buffered saline with 0.05% Tween 20), cell

membranes were incubated overnight at 4°C with primary antibodies (1:1000 for anti-ERK from Cell Signaling Technology; 1:2000 for anti-pERK from Cell Signaling Technology, Boston, MA, USA). The membranes were then incubated with their corresponding secondary HRP-conjugated antibodies and detected using an ECL Western blotting detection system (Millipore, Boston, MA, USA). Densitometric analysis was performed using a Bio-Rad image acquisition system (Bio-Rad Laboratories, Hercules, CA, USA).

Culture of hippocampal neurons and whole-cell patch-clamp

Hippocampal explants were isolated from embryos of 18-day-old Sprague-Dawley rats of either sex after decapitation. Hippocampal regions were gently removed and digested with 0.25% trypsin for 30 min at 37°C followed by trituration with a pipette in plating medium (DMEM with 10% FBS). Dissociated neurons were plated onto poly-D-lysine coated coverslips in 35-mm dishes at a density of 1×10^6 cells per dish. After 4 h, the medium was displaced by neurobasal medium supplemented with 2% B27 and 0.5 mmol/L GlutaMAX-I (Life Technologies, Carlsbad, CA, USA).

For whole-cell recordings, cells were held at -80 mV and recorded using a HEKA EPC10 amplifier with PatchMaster software (HEKA Elektronik, Pfalz, Germany). Patch pipettes were pulled from borosilicate glass and fire-polished to a resistance of 3–5 $\text{M}\Omega$ when filled with internal pipette solution composed of the following (in mmol/L): 126 CsCH_3SO_3 , 10 CsCl, 4 NaCl, 1 MgCl_2 , 0.5 CaCl_2 , 5 EGTA, 10 HEPES, 3 ATP-Mg, 0.3 GTP-Na, and 4 phosphocreatine, pH 7.2. Cells were perfused with the external solution containing (in mmol/L): 140 NaCl, 5 KCl, 2 CaCl_2 , 1 MgCl_2 , 10 HEPES, and 10 glucose, pH 7.4. Atropine (5 $\mu\text{mol}/\text{L}$), CNQX (5 $\mu\text{mol}/\text{L}$), bicuculline (10 $\mu\text{mol}/\text{L}$) and tetrodotoxin (0.5 $\mu\text{mol}/\text{L}$) were included in the bath solution throughout experiments.

Hippocampal brain slice electrophysiology

Male Sprague-Dawley rats (14–21 day-old) were deeply anesthetized with sodium pentobarbital (250 mg/kg) before decapitation. Brains were quickly removed and placed into ice-cold artificial cerebrospinal fluid (ACSF) containing (in mmol/L): 119 NaCl, 2.5 KCl, 2.5 CaCl_2 , 1.3 MgSO_4 , 1 NaH_2PO_4 , 26.2 NaHCO_3 , and 11 glucose, and bubbled with 95% O_2 /5% CO_2 . Transverse hippocampal slices (400 μm) were cut with a vibratome (Leica VT1200S, Leica, Wetzlar, Germany). The slices were incubated for 1 h at 34°C with ACSF and then transferred to a recording chamber on an upright microscope equipped with differential interference contrast (DIC) optics (Nikon FN1, Tokyo, Japan). For IPSC recordings, whole-cell patch clamp configurations were routinely achieved from CA1 hippocampal pyramidal neurons visualized with a DIC microscope. Patch pipette (3–5 $\text{M}\Omega$) solution contained (in mmol/L): 136 CsCl, 4 NaCl, 1 MgCl_2 , 0.5 CaCl_2 , 5 EGTA, 10 HEPES, 3 Mg-ATP, 0.3 GTP-Na, 4-phosphocreatine (pH adjusted to 7.2 with CsOH and osmolarity adjusted to 290 mOsm). According to the Nernst equation, the reversal potential of Cl^- was approximately 3 mV at room temperature.

Therefore, when neurons were held at -70 mV, the spontaneous IPSCs were inward. To block fast excitatory synaptic current (EPSC), 5 $\mu\text{mol/L}$ CNQX (in DMSO) and 10 $\mu\text{mol/L}$ APV were added to ACSF. Atropine (5 $\mu\text{mol/L}$) was used to block muscarinic receptors. Voltage-clamp recordings were conducted with a computer-controlled amplifier (Multiclamp 700B, Molecular Devices, Sunnyvale, CA, USA), and traces were low-pass filtered at 2.6 kHz and digitized at 10 kHz (DigiData 1440A, Molecular Devices, Sunnyvale, CA, USA). Neurons with stable access resistance were included in the analysis.

Data analysis

All data are expressed as the mean $\pm$ SEM. Statistical significance was assessed by Student's *t*-test or one-way ANOVA using Prism version 5.0 software. A value of $P < 0.05$ was considered statistically significant. In two-electrode voltage clamp and whole-cell patch clamp recordings, responses were quantified by measuring peak current amplitude, and data were collected and analyzed using PatchMaster and Origin 8.0 software. For hippocampal brain slice electrophysiology, the data were collected and analyzed using Clampfit 10.4 or Clampex 10.4 software. All concentration-response curves were fitted to the Hill equation as follows: $I_{\text{normalized}} = E_{\text{max}} / (1 + (\text{EC}_{50} / C)^{n_{\text{H}}})$. For radioisotope ligand binding assay, the dissociation constant K_i was determined from the equation $K_i = \text{IC}_{50} / (1 + L / K_D)$.

Results

Screening $\alpha 7$ nAChR agonists by two-electrode voltage clamp

To identify novel $\alpha 7$ agonists, we started with a computer-aided virtual screen and performed structural optimizations using the compound EVP-6124, which is in a phase II clinical trial, as a reference structure^[21]. The substructure search for $\alpha 7$ nAChR agonists from the SureChEMBL database revealed that N-(quinuclidin-3-yl) formamide appeared frequently, and its similarity search (SS) was performed based on the MACCS structural fingerprint^[25]. Approximately 400 compounds were selected, and they clustered into 20 categories. Among the SS-selected compounds, an indolizine-3-carboxylic acid derivative was reported to block the 5-HT₃ receptor, which shares significant homology with $\alpha 7$ nAChR^[26, 27]. Thus, an indolizine-3-carboxylic acid derivative was used as a hit for structural modifications that were primarily focused on the indolizine moiety by changing the substitution group at different positions. Over 60 compounds were synthesized, and their activities were tested on human $\alpha 7$ nAChR transiently expressed in *Xenopus* oocytes using two-electrode voltage clamp. Compounds that were able to evoke $\alpha 7$ currents were further assessed for their potency and relative efficacy against acetylcholine. EC_{50} values of positive compounds were generated by fitting Hill equations, and their maximal effects were normalized to 3 mmol/L ACh from the same cell. Based on the criteria that compounds must have a minimal EC_{50} and an efficacy of at least 60% that of ACh, one compound, N-[(3R)-1-azabicyclo[2,2,2]oct-3-yl]-5-bromoindolizine-2-carboxamide

(Br-IQ17B, MW=348.24) was identified as an ideal lead (Figure 1A). Therefore, Br-IQ17B was further evaluated for its effects on $\alpha 7$ currents.

Dose-dependent activation of $\alpha 7$ currents by Br-IQ17B

As shown in Figure 1B, the activation of $\alpha 7$ by ACh was first performed as a control before repeated applications of Br-IQ17B. With a 7-min pulse interval between each dose, increasing concentrations of Br-IQ17B dose-dependently activated $\alpha 7$ nAChR with a maximum efficacy of $64.3\% \pm 3.6\%$ compared with 3 mmol/L ACh (Figure 1C). The data from dose-dependent activation were fitted with the Hill equation, yielding an EC_{50} of $1.8 \pm 0.2 \mu\text{mol/L}$ and a Hill coefficient of 1.2 ± 0.1 ($n=6$) (Figure 1C). The current induced by Br-IQ17B (30 $\mu\text{mol/L}$) was completely blocked by 10 nmol/L MLA, an $\alpha 7$ nAChR selective antagonist (Figure 1D), indicating that Br-IQ17B mediated its effects through specific $\alpha 7$ activation. To further confirm the agonist activity of Br-IQ17B, we tested Br-IQ17B in the presence of the $\alpha 7$ positive allosteric modulator (PAM) PNU-120596, which is known to enhance the activation of $\alpha 7$ by ACh^[28]. As shown in Figure 2A, co-application of Br-IQ17B with a fixed concentration of PNU-120596 (1 mmol/L) resulted in a dose-dependent activation of $\alpha 7$ currents. The potency of Br-IQ17B was increased from $1.8 \pm 0.2 \mu\text{mol/L}$ to $93.6 \pm 6.5 \text{ nmol/L}$ ($n=6$), and the Hill slope was increased from 1.2 ± 0.1 to 2.4 ± 0.1 compared with Br-IQ17B alone, which showed partial activation (Figure 2B).

One of the key properties of $\alpha 7$ current is robust desensitization upon repeated exposures to an agonist^[29]. To test whether Br-IQ17B could cause desensitization, we used a double protocol in which oocytes were exposed to sustained (1 min) increasing concentrations of Br-IQ17B before the addition of a fixed and low concentration of ACh (100 $\mu\text{mol/L}$). As shown in Figure 2C, 100 $\mu\text{mol/L}$ ACh produced a robust $\alpha 7$ current. In contrast, the incubation of different concentrations of Br-IQ17B decreased the amplitude of $\alpha 7$ current in the presence of the same concentration of ACh (100 $\mu\text{mol/L}$). Plotting the amplitude of the current evoked by ACh as a function of increasing Br-IQ17B yielded a concentration-dependent inhibition of ACh-induced $\alpha 7$ current with an IC_{50} at $28.5 \pm 1.9 \text{ nmol/L}$ and a Hill coefficient at 2.8 ± 0.3 (Figure 2D), which is in good agreement with the K_i of $14.9 \pm 3.2 \text{ nmol/L}$ for the displacement of [³H]-MLA binding at $\alpha 7$ nAChR. It is noteworthy that the low concentration of Br-IQ17B (3 nmol/L) that had no agonist activity increased the ACh-mediated peak current, whereas the current desensitization became apparent for Br-IQ17B at 10 nmol/L or greater concentration (Figure 2C and 2D).

Displacement of [³H]-MLA binding to $\alpha 7$ nAChR by Br-IQ17B

$\alpha 7$ nAChR agonists can displace the binding of the specific competitive antagonist [³H]-MLA to the $\alpha 7$ nAChR extracellular N-terminal domain, which contains the orthosteric binding sites^[30]. To assess whether Br-IQ17B could affect [³H]-MLA binding, we prepared hippocampal crude membranes from rat hippocampi that contain nAChRs and conducted the

Figure 1. Chemical structure of Br-IQ17B and its dose-dependent activation of human $\alpha 7$ nAChR channels expressed in *Xenopus* oocytes. (A) Chemical structure of N-[(3R)-1-azabicyclo[2,2,2]oct-3-yl]-5-bromoindolizine-2-carboxamide, named Br-IQ17B, molecular weight of 348.24. (B) Representative $\alpha 7$ currents recorded from an oocyte expressing human $\alpha 7$ nAChR in response to 300 $\mu\text{mol/L}$ ACh (a near half-maximal concentration) and increasing concentrations of Br-IQ17B (0.1–30 $\mu\text{mol/L}$). Oocytes were held at -90 mV, and traces were consecutively acquired with 7-min lapses. (C) Curve with open squares represents concentration-response relationship of inward $\alpha 7$ nAChR currents induced by Br-IQ17B. The maximal response evoked by Br-IQ17B is $64.3\pm 3.6\%$ of ACh (3 mmol/L) with an EC_{50} of 1.8 ± 0.2 $\mu\text{mol/L}$ and a Hill coefficient of 1.2 ± 0.1 ($n=6$ for all data points). Curve with fitted triangles represents concentration-response of EVP-6124 with an EC_{50} of 0.45 ± 0.08 $\mu\text{mol/L}$ and a Hill coefficient of 1.2 ± 0.2 ($n=6$ for all data points). The maximal response compared to ACh is $30.6\pm 1.8\%$. Curve with fitted circles represents concentration-response of natural agonist ACh, yielding an EC_{50} of 284.2 ± 14.6 $\mu\text{mol/L}$ and a Hill coefficient of 1.1 ± 0.1 ($n=6$ for all data points). Peak current amplitudes were measured and normalized to the current evoked by 3 mmol/L ACh. (D) The $\alpha 7$ current evoked by 30 $\mu\text{mol/L}$ Br-IQ17B was inhibited by 10 nmol/L $\alpha 7$ antagonist MLA. The inhibitory effect could be reversed after a 10-min washout.

radioisotope ligand binding assay. As shown in Figure 3, Br-IQ17B displaced the [^3H]-MLA binding to crude membranes in a concentration-dependent manner with a K_i value of 14.9 ± 3.2 nmol/L ($n=3$), which is approximately 300-fold more potent than the natural agonist ACh ($K_i=3.9\pm 0.3$ $\mu\text{mol/L}$). PNU-282987, a selective $\alpha 7$ nAChR agonist, is known to bind to $\alpha 7$ nAChR^[31]. As another positive control, the inhibitory effect of PNU-282987 on [^3H]-MLA binding was determined. PNU-282987 dose-dependently displaced the binding of [^3H]-MLA with a K_i of 34.1 ± 4.3 nmol/L, which is similar to the K_i value as previously described^[32]. These results show that Br-IQ17B can competitively bind to $\alpha 7$ nAChR.

Selective activation of $\alpha 7$ by Br-IQ17B

To determine the selectivity of Br-IQ17B, we examined the effects of Br-IQ17B on $\alpha 4\beta 2$ and $\alpha 3\beta 4$, two nAChR subtypes that exhibit distributions that are similar to that of $\alpha 7$ nAChR in the brain^[33]. The expression of rat $\alpha 4\beta 2$ or $\alpha 3\beta 4$ in *Xenopus*

oocytes produced a robust current in response to either 100 or 300 mmol/L ACh (Figure 4A and 4B). The application of Br-IQ17B (100 mmol/L) did not induce any current (Table 1). The lack of effect on $\alpha 4\beta 2$ was further confirmed by either pre-incubation of Br-IQ17B for 1 min or the co-application of Br-IQ17B with ACh, which resulted in no enhancement or inhibition of $\alpha 4\beta 2$ current (Figure 4A). This result indicates that

Table 1. Selectivity of Br-IQ17B on nAChR subtypes and 5-HT_{3A} receptor determined by TEVC.

Target	EC_{50} ($\mu\text{mol/L}$)	Maximum effect vs 3 mmol/L ACh or 10 $\mu\text{mol/L}$ 5-HT	n
$\alpha 7$, Human	1.8 ± 0.21	$64.3\pm 3.6\%$	6

Figure 2. Dose-dependent activation of $\alpha 7$ current by Br-IQ17B agonist in the presence of the PAM PNU-120596 and desensitization induced by pre-incubation of Br-IQ17B. (A) Representative traces induced by increasing concentrations of Br-IQ17B co-applied with the selective $\alpha 7$ type II PAM PNU-120596 (1 $\mu\text{mol/L}$). Oocytes were held at -90 mV, and traces were consecutively acquired with 7-min lapses. (B) Concentration-peak current of $\alpha 7$ induced by Br-IQ17B in the presence of 1 $\mu\text{mol/L}$ PNU-120596 and fitted by the Hill equation (line with open squares), with an EC_{50} of 93.6 $\pm$ 6.5 nmol/L and a Hill coefficient of 2.4 $\pm$ 0.1 ($n=5$ for all data points); partial activation of $\alpha 7$ by Br-IQ17B alone with EC_{50} of 1.8 $\pm$ 0.2 $\mu\text{mol/L}$ (line with filled circles). (C) Representative current traces depicting the response to ACh (100 $\mu\text{mol/L}$) after 1-min sustained exposure to low concentrations of Br-IQ17B (3–300 nmol/L). Oocytes were held at -90 mV, and consecutive acquisitions of traces were made with 7-min lapses. (D) Fitting of concentration-dependent inhibition of the ACh (100 $\mu\text{mol/L}$)-evoked response after sustained exposure to Br-IQ17B. Peak current amplitudes were measured and normalized with respect to the amplitude of current elicited by 100 $\mu\text{mol/L}$ ACh alone. Data points were fitted to a Hill equation, yielding an IC_{50} of 28.5 $\pm$ 1.9 nmol/L and a Hill coefficient of 2.8 $\pm$ 0.3 ($n=6$ for all data points).

Br-IQ17B had no effect on $\alpha 4\beta 2$. For $\alpha 3\beta 4$, Br-IQ17B showed an inhibitory effect with an IC_{50} of approximately 381.5 $\pm$ 28.6 $\mu\text{mol/L}$ and a Hill coefficient of 0.9 $\pm$ 0.1 ($n=5$) (Figure 4B), thus displaying at least 300-fold selectivity over $\alpha 3\beta 4$ (Figure 4C). The 5-HT_{3A} receptor has significant homology with $\alpha 7$ nAChR and serves as a cross-reactivity target for $\alpha 7$ agonists. Br-IQ17B alone (0.1–100 $\mu\text{mol/L}$) did not show any agonist activities on human 5-HT_{3A} receptors expressed in oocytes. The co-application of Br-IQ17B with serotonin dose-dependently inhibited the current induced by 5-HT (10 $\mu\text{mol/L}$) with an IC_{50} of 3.74 $\pm$ 0.64 $\mu\text{mol/L}$ ($n=6$) and a Hill coefficient of 2.1 $\pm$ 0.1 (Figure 4D and 4E, Table 2).

Activation of native neuronal $\alpha 7$ nAChR by Br-IQ17B

Hippocampal somatic neurons express $\alpha 7$ nAChR or ACh-evoking characteristic $\alpha 7$ currents that can be activated by $\alpha 7$ agonists^[34]. To evaluate whether Br-IQ17B can activate native $\alpha 7$ nAChR, we examined the effects of Br-IQ17B on hippocampal neurons. As shown in Figure 5A, the application of

Table 2. Inhibition of ACh-evoked nAChR subtype and serotonin-evoked 5-HT_{3A} currents by Br-IQ17B in TEVC.

Target	IC_{50} (nmol/L)	n
$\alpha 7$, Human	28.5 $\pm$ 2.5 vs 100 $\mu\text{mol/L}$ ACh	6
$\alpha 4\beta 2$, Rat	>100 000 vs 100 $\mu\text{mol/L}$ ACh	6
$\alpha 3\beta 4$, Rat	381 510 $\pm$ 52 251 vs 300 $\mu\text{mol/L}$ ACh	5
5-HT _{3A} , Human	3740 $\pm$ 90 vs 10 $\mu\text{mol/L}$ 5-HT	6

either ACh (1 mmol/L) or Br-IQ17B (10 $\mu\text{mol/L}$) evoked $\alpha 7$ currents with fast onset and rapid decay. Br-IQ17B evoked currents were sensitive to the $\alpha 7$ antagonist MLA (10 nmol/L), which completely blocked the native $\alpha 7$ current, and the inhibitory effect can be washed out (Figure 5A). We further tested whether the Br-IQ17B-evoked native $\alpha 7$ current can be augmented in the presence of the PAM PNU-120596. A low concentration of ACh (10 mmol/L) evoked an observable $\alpha 7$

Figure 3. Displacement of [3 H]-MLA ligand binding in crude membranes from rat brain. Displacement of the binding of the radio-ligand $\alpha 7$ antagonist [3 H]-MLA to membranes of rat brain hippocampus in the presence of increasing concentrations of Br-IQ17B (line with open squares) and natural agonist ACh (line with filled triangles) with K_S of 14.9 ± 3.2 nmol/L and 3.9 ± 0.3 μ mol/L, respectively. The line with filled circles shows the dose-dependent inhibition of [3 H]-MLA binding by the orthosteric agonist PNU-282987 as positive control, yielding a K_i of 34.1 ± 4.3 nmol/L.

current in neurons that could be robustly increased in the presence of PNU-120596 (1 mmol/L) (Figure 5B). Similarly, a low concentration of Br-IQ17B (100 nmol/L) activated a small current that was significantly enhanced by the co-application of PNU-120596 (1 mmol/L), further confirming that the agonist Br-IQ17B can activate native neuronal $\alpha 7$ current (Figure 5B).

Enhanced phosphorylation of ERK signaling by Br-IQ17B in PC12 cells

The activation of native $\alpha 7$ nAChR results in enhanced ERK (extracellular signal-regulated kinases) phosphorylation and signaling that is implicated in the regulation of a variety of physiological functions such as cognition enhancement^[35]. To test whether Br-IQ17B had any effect on ERK signaling, we evaluated ERK phosphorylation upon $\alpha 7$ activation in rat PC12 cells, which have intact ERK signaling and robustly expressed pathway components. Because $\alpha 7$ nAChR is rapidly desensitized upon activation, agonist-evoked responses are not easily detectable by conventional methods that are insufficient for the measurement of rapid effects. To overcome this shortcoming, PNU-120596 has successfully been used as a tool to slow the receptor desensitization, thus leading to easy detection of compound response. As shown in Figure 6A, the pre-incubation of PC12 cells with PNU-120596 for 10 min only caused a slight increase of the basal ratio of phosphorylated ERK (pERK1 and pERK2) over total ERK (tERK). In contrast, the pre-incubation of the PAM PNU-120596 with Br-IQ17B (0.01–10 mmol/L) for an additional 7 min significantly increased the pERK/tERK ratio in a concentration-dependent manner (Figure 6A). The maximal increase of the pERK/tERK ratio was approximately 3–4 fold compared with either the blank control or the pre-incubation control without Br-IQ17B.

To further confirm whether Br-IQ17B-induced ERK1/2 phosphorylation was mediated by the activation of $\alpha 7$ nAChR, several tool compounds including the selective antagonist MLA (100 nmol/L), the selective $\alpha 7$ agonist PNU-282987 (1 μ mol/L), and the traditional non-selective $\alpha 7$ agonist nicotine (10 μ mol/L) were utilized to test any specific activation of ERK signaling by Br-IQ17B. As shown in Figure 6B, the incubation of MLA (100 nmol/L) significantly reversed the activation of $\alpha 7$ induced by the agonists, confirming that the enhanced level of pERK is $\alpha 7$ activity dependent.

Enhancement of GABAergic synaptic transmission by $\alpha 7$ nAChR agonist Br-IQ17B

In the hippocampus, $\alpha 7$ nAChR subunits are primarily expressed in GABAergic interneurons, therefore we predicted that the $\alpha 7$ nAChR agonist Br-IQ17B might have an impact on GABAergic transmission. To test this notion, we recorded spontaneously occurring inhibitory postsynaptic current (sIPSC) from CA1 pyramidal neurons that receive inputs from interneurons in response to challenges with Br-IQ17B (10 μ mol/L), PNU-120596 (1 μ mol/L), or a combination of Br-IQ17B and PNU-120596 (Figure 7A and 7B). To block glutamatergic synaptic transmissions and muscarinic AChR, spontaneous IPSCs were recorded in the presence of glutamate receptor antagonists (CNQX 5 μ mol/L, APV 10 μ mol/L) and a muscarinic receptor antagonist (atropine 5 μ mol/L). When applied alone for 10 min, PNU-120596 produced no detectable changes in the average frequency or amplitude of sIPSC at the population level (Figure 7B and 7C) (baseline activity at 4.5 ± 0.7 Hz *vs* 4.6 ± 0.7 Hz in the presence of PNU-120596; $n=6$, $P>0.05$; amplitude of 30.8 ± 6.8 pA *vs* 30.6 ± 4.7 pA in the presence of PNU-120596; $n=6$, $P>0.05$). In contrast, in the combined presence of Br-IQ17B and PNU120596, the peak amplitudes of IPSC events of individual neurons were significantly increased from 1.3 to 4.9 times in 5 out of 6 neurons recorded ($P<0.0001$) compared with control or PNU120596 alone (Figure 7B and 7C). After the co-application of PNU-120596 with Br-IQ17B for 1–5 min, the IPSC frequency also increased from 4.6 ± 0.7 Hz to 7.8 ± 0.7 Hz ($n=6$, $P<0.01$), and the combined effects of both Br-IQ17B and PNU120596 could be completely washed out (Figure 7D). For one neuron out of six, the co-application of Br-IQ17B and PNU-120596 promoted IPSC frequency without affecting IPSC amplitude (25.3 ± 1.4 pA *vs* 25.9 ± 1.2 pA). These results demonstrate that $\alpha 7$ nAChR activation by the novel agonist Br-IQ17B enhances synaptic transmissions in hippocampal neurons.

To further examine if the enhancement of IPSC resulted from an increase of GABAergic synaptic transmission, we tested the effect of Br-IQ17B on GABA_A receptors with combinations of $\alpha 1\beta 3\gamma 2$, $\alpha 2\beta 3\gamma 2$, and $\alpha 3\beta 3\gamma 2$, which are the major subtypes in the brain^[36, 37]. Although the $\alpha 5$ subunit accounts for less than 5% of GABA_A receptors in brain, we also tested the selectivity on $\alpha 5\beta 3\gamma 2$ because the $\alpha 5$ subtype is primarily localized in the hippocampus^[38]. As shown in Figure 8, after pre-incubation for 1 min, Br-IQ17B (100 μ mol/L) had no observable effects on any of the four subtypes and displayed no allosteric modulation when co-applied with 1 μ mol/L

Figure 4. Selectivity assessments of Br-IQ17B. (A) Representative current traces showing the effects of Br-IQ17B on an oocyte expressing rat $\alpha 4\beta 2$ nAChR in the presence of 100 $\mu\text{mol/L}$ ACh (left), 100 $\mu\text{mol/L}$ Br-IQ17B (middle), and the co-application of ACh and Br-IQ17B (right). (B) Representative current traces showing the effects of Br-IQ17B on an oocyte expressing $\alpha 3\beta 4$ nAChR subunits in the presence of ACh (300 $\mu\text{mol/L}$) (left), or different concentrations (3–3000 $\mu\text{mol/L}$) of Br-IQ17B alone (middle), or the co-application of different concentrations of Br-IQ17B ranging from 3–3000 $\mu\text{mol/L}$ (only 3 traces for concentrations of 10, 100 and 1000 $\mu\text{mol/L}$ are shown) with a fixed concentration of ACh (300 $\mu\text{mol/L}$) (right). (C) Concentration-response curve for inhibition of Br-IQ17B on rat $\alpha 3\beta 4$; the peak current amplitudes were plotted as a function of Br-IQ17B concentration (3–3000 $\mu\text{mol/L}$) normalized to ACh (300 $\mu\text{mol/L}$), with an IC_{50} of 381.5 ± 28.6 $\mu\text{mol/L}$ and a Hill coefficient of 0.9 ± 0.1 ($n=5$ for all data points). (D) Representative current traces from oocytes expressing 5-HT_{3A} receptors in response to 100 $\mu\text{mol/L}$ Br-IQ17B alone (first trace), 10 $\mu\text{mol/L}$ 5-HT alone, and the co-application of increasing concentrations of Br-IQ17B (0.3–30 $\mu\text{mol/L}$) with 5-HT (10 $\mu\text{mol/L}$). (E) Concentration-response relationship for antagonist properties of Br-IQ17B against human 5-HT_{3A}; plot of the peak current as a function of the Hill equation of Br-IQ17B (0.1–100 $\mu\text{mol/L}$) and normalized to 5-HT (10 $\mu\text{mol/L}$), with an IC_{50} of 3.74 ± 0.64 $\mu\text{mol/L}$ and a Hill coefficient of 2.1 ± 0.1 ($n=6$ for all data points).

GABA. These results show that enhanced GABAergic synaptic transmission likely resulted from the direct activation of $\alpha 7$ nAChR by Br-IQ17B.

Discussion

The goal of this study was to identify novel potent $\alpha 7$ nAChR agonists. Using electrophysiology as a primary screen, we identified the novel and potent compound Br-IQ17B from a series of indolizine derivatives; this compound selectively activates $\alpha 7$ nAChR and enhances synaptic transmission *in vitro*. Our $\alpha 7$ agonist Br-IQ17B, N-[(3R)-1-azabicyclo[2,2,2]oct-3-yl]-5-bromoindolizine-2-carboxamide, adds a novel tool in

the field that may help understand new aspects of $\alpha 7$ nAChR function and also provides the potential for the development of novel therapy. Br-IQ17B exhibits some typical characteristics of $\alpha 7$ agonists reported in literature. One of the key characteristics is that the sustained exposure of Br-IQ17B progressively prevented ACh from activating $\alpha 7$ nAChR in *Xenopus* oocytes, whereas the pre-incubation of low concentration of Br-IQ17B potentiated ACh-mediated current. The most plausible explanation is the co-agonistic behavior of agonists binding at low concentrations, as previously reported for tubocurarine and ACh at $\alpha 3\beta 4$ nAChRs^[39].

In this study, we selected compound EVP-6124 as a ref-

Figure 5. Activation of native $\alpha 7$ nAChR in hippocampal neurons by Br-IQ17B. (A) Representative current traces evoked by agonist ACh (1 mmol/L) and Br-IQ17B (10 μ mol/L) in hippocampal neurons. The current elicited by Br-IQ17B was blocked by the inhibitor MLA (10 nmol/L) ($n=3$). The neurons were held at -80 mV. (B) Representative current traces evoked by a low concentration of ACh (10 μ mol/L) or Br-IQ17B (100 nmol/L) in the presence or absence of PNU-120596 (1 μ mol/L), respectively ($n=3$). Current induced by the co-application of Br-IQ17B (100 nmol/L) and PNU-120596 (1 μ mol/L) is significantly larger than Br-IQ17B (100 nmol/L) alone. The neurons were held at -80 mV.

erence. In comparison to EVP-6124 from the oocyte assay (Figure 1C), although the EC_{50} of Br-IQ17B (1.8 ± 0.2 μ mol/L) is greater than that of EVP-6124 (0.45 ± 0.08 μ mol/L), the maximal response from Br-IQ17B is more than doubled that of EVP-6124 ($64.3 \pm 3.6\%$ vs $30.6 \pm 1.8\%$). Thus, Br-IQ17B may possess better efficacy in the enhancement of $\alpha 7$ activity. Furthermore, the concentration of EVP-6124 needed to reach 30% of the response (maximal response of EVP-6124) of ACh is 3 μ mol/L, whereas for Br-IQ17B it is only 1.5 μ mol/L. All of these findings suggest that Br-IQ17B may have advantages over EVP-6124.

The identification of selective $\alpha 7$ agonists for CNS therapy is a huge challenge in the field; three different $\alpha 7$ agonists in phase I clinical studies, PHA-543613, PHA-568487, and CP-810123 were recently discontinued due to non-sustained ventricular tachycardia^[23], and the nonspecific nicotinic ligand varenicline has been associated with serious adverse cardiovascular events^[24]. It is not known whether these cardiovascular events are related to the activation of $\alpha 7$ nAChR or other pharmacological mechanisms, but compounds such as EVP-6124 suggest that the $\alpha 7$ nAChR can be targeted safely in clinical trials^[21]. Because drugs with less selectivity that target multiple unintended receptors may be insufficient to prevent the incidence of side effects, especially gastrointestinal ones, it is necessary to evaluate the selectivity of Br-IQ17B on other nAChR subtypes. In the present study, we were concerned that Br-IQ17B could have activity against $\alpha 3\beta 4$ and $\alpha 4\beta 2$ nAChRs, which have similar distribution patterns

Figure 6. Activation of $\alpha 7$ nAChR by Br-IQ17B enhances pERK signaling in PC12 cells. (A) In the upper panel, Western blot analysis of PC12 cells stimulated with different concentrations of Br-IQ17B (0.01–10 μ mol/L) for 7 min after pre-incubation of 1 μ mol/L PNU-120596 for 10 min. Lower panel, semi-quantitative analysis of pERK/total ERK from upper panel data. Data were normalized to that of control without any treatment and expressed as the mean $\pm$ SEM. Co-application of PNU-120596 (1 μ mol/L) and Br-IQ17B significantly increased the ratio of phosphorylated ERK to total ERK ($n=3$, $^*P<0.01$ vs control, paired t -test). (B) In upper panel, the Br-IQ17B-increased phosphorylation of ERK1/2 was blocked in the presence of the $\alpha 7$ blocker MLA. Western blot analysis of PC12 cells pretreated with or without 100 nmol/L MLA for 10 min followed by the addition of 1 μ mol/L PNU-120596 and agonists (10 μ mol/L for nicotine; 1 μ mol/L for Br-IQ17B, and 1 μ mol/L for PNU-282987). Lower panel, semi-quantitative analysis of pERK/total ERK from upper panel data. Data were normalized to that of control without any treatment and expressed as the mean $\pm$ SEM. MLA significantly reversed the increased ratio of phosphorylation ERK caused by either Br-IQ17B or PNU-282987 ($n=3$, $^bP<0.05$, paired t -test).

Figure 7. $\alpha 7$ nAChR agonist Br-IQ17B enhances GABAergic synaptic transmission. (A) Representative raw traces showing that Br-IQ17B (10 μ mol/L) reversibly enhanced IPSC (inhibitory postsynaptic current) in the presence of PNU-120596 (1 μ mol/L). Superfusion of PNU-120596 alone for 10 min had no detectable effect on spontaneous IPSC (sIPSC); further application of Br-IQ17B (10 μ mol/L) increased both the frequency and amplitude of sIPSC. Enhanced sIPSC induced by the co-application of PNU-120596 and Br-IQ17B can be washed out. The area of the dashed rectangle (left panels) is expanded to show a faster timescale at right. The neurons were held at -70 mV. (B) Peak amplitude distributions of all IPSC events detected in the left panel of (A). Co-application of Br-IQ17B and PNU-120596 significantly increased IPSC amplitudes ($^cP < 0.01$, compared with control, PNU-120596 and wash, one-way ANOVA). (C) Normalized average IPSC peak amplitudes from all recordings. Co-application of Br-IQ17B and PNU-120596 increased IPSC amplitude of each individual neuron ($n = 5$, record duration for 1 min, one-way ANOVA). (D) Statistical analysis of average IPSC frequency from all neurons recorded ($n = 6$, record duration for 1 min). Co-application of Br-IQ17B and PNU-120596 significantly increased average IPSC frequency ($^bP < 0.05$ vs control, $^cP < 0.01$ vs PNU-120596 or wash, paired *t*-test).

as $\alpha 7$ nAChR in CNS^[33], and the nonspecific nicotinic ligands always have cross reactivity on these receptors (eg, nicotine, varenicline). In oocytes, Br-IQ17B showed no detectable agonist activity at up to 100 μ mol/L toward either the $\alpha 3\beta 4$ and $\alpha 4\beta 2$ subtypes and very weak antagonist activity against $\alpha 3\beta 4$ ($IC_{50} \approx 381$ μ mol/L).

The 5-HT_{3A} belongs to the superfamily of ligand-gated ion channels. Significant sequence homology between 5-HT_{3A} and $\alpha 7$ nAChR including the ligand-binding domain can lead to the cross-reactivity of certain compounds (eg, tropisetron)^[27]. Br-IQ17B inhibited 5-HT-induced current but did not evoke currents when applied alone. The antagonist activity of Br-IQ17B against 5-HT_{3A} receptors is likely a common property of $\alpha 7$ nAChR agonists, such as that reported for AZD0328^[40] and EVP-6124^[41], which are still in clinical development.

Stimulating $\alpha 7$ nAChR increases intracellular Ca^{2+} , either

directly or via voltage-gated calcium channels, and leads to the activation of Raf^[42] and the subsequent activation of the ERK1/2 signaling pathway, thus allowing the phosphorylation of cytoplasmic ERK substrates^[43]. The ERK1/2 pathway is a central component in signal transduction regulating synaptic targets to control plasticity, and it is implicated in the processes of learning and memory^[44]. PC12 cells express native $\alpha 7$ nAChR and are utilized for measuring the activation of native $\alpha 7$ nAChR^[45, 46]. Not only the non-specific nAChRs agonist nicotine but also the selective $\alpha 7$ nAChR agonist A-582941 have been proposed to stimulate the phosphorylation of ERK1/2 both *in vitro* and *in vivo*^[47]. In our study, we assessed the phosphorylation of ERK1/2 in response to the activation of $\alpha 7$ nAChR by Br-IQ17B within PC12 cells, and a significant concentration-dependent increase in ERK1/2 phosphorylation was observed, indicating that the ERK1/2 pathway is a down-

Figure 8. Selectivity assessments of Br-IQ17B on subtypes of GABA_A receptors. Representative current traces recorded in oocytes expressing human $\alpha 1\beta 3\gamma 2$ (A), $\alpha 2\beta 3\gamma 2$ (B), $\alpha 3\beta 3\gamma 2$ (C), and $\alpha 5\beta 3\gamma 2$ (D) subtypes showing the lack of effects of Br-IQ17B on GABA_A activity in the presence of 1 $\mu\text{mol/L}$ GABA (left), 100 $\mu\text{mol/L}$ Br-IQ17B (middle), or the co-application of GABA and Br-IQ17B (right) ($n=3$ for all subtypes).

stream effector of $\alpha 7$ activation.

It has well been established that within the rat hippocampus, $\alpha 7$ nAChR is located predominantly in interneurons where it modulates GABAergic synaptic transmission involved in sensory gating^[48]. Deficits in auditory sensory gating can lead to an inability to filter out extraneous signals from meaningful sensory inputs, resulting in a state of sensory overload, which contributes to the attentional and cognitive deficits in CNS diseases, most convincingly in schizophrenia^[49]. It has been shown that the $\alpha 7$ nAChR partial agonist GTS-21 [3-(2,4)-dimethoxybenzylidene anabaseine], also known as DMXB-A, appears to be safe and promising for improving P50 gating deficits and attention, and it significantly improves neurocognition in schizophrenia patients with antipsychotic drugs^[50, 51]. GABA is an inhibitory synaptic transmitter, and its decreased release can lead to the disinhibition of sensory gating (eg, the deficit of P50 auditory-evoked potential gating is indicated in some schizophrenic patients). To evaluate the ability of Br-IQ17B to modulate GABAergic synaptic transmission, we recorded sIPSC in pyramidal neurons in acutely isolated rat hippocampal slices. The spontaneous GABAergic synaptic events were recorded for 3 to 5 min under baseline conditions, followed by a 10-min pre-incubation of PNU-120596 before the addition of Br-IQ17B for 5 min. In agreement with the previously reported role of $\alpha 7$ nAChR in the hippocampus, there was no detectable change in synaptic activity after the application of PNU-120596 alone, whereas the bath application of 10 $\mu\text{mol/L}$ Br-IQ17B doubled the frequency and increased the amplitude significantly.

In conclusion, we identified Br-IQ17B as a novel and selec-

tive $\alpha 7$ nAChR agonist that exhibits favorable potency and efficacy. Br-IQ17B is a prominent candidate that provides opportunities for further investigations in CNS pharmacology. It also serves as a suitable tool for characterizing the role of $\alpha 7$ nAChR in CNS function, and it may have the potential for development into new therapy for CNS disorders.

Acknowledgements

We would like to thank Tim G HALES at the University of Dundee for the generous gift of the human 5-HT_{3A} cDNA clone and Lucia G SIVILOTTI at University College London for rat $\alpha 3$ and $\beta 4$ cDNA clones. We thank laboratory member Yan SONG for technical assistance. We also thank Ming JI and Xiao-guang CHEN for technical assistance in radioisotope ligand binding. Ke-wei WANG wishes to thank JM WANG for her consistent support during this research. This work was supported by research grants to Ke-wei WANG from the Ministry of Science and Technology of China (2013CB531302 and 2014ZX09507003-006-004) and the National Natural Science Foundation of China (31370741 and 81221002), to Liang-ren ZHANG from the National Natural Science Foundation of China (81373272) and to Xi-ling BIAN from Beijing Higher Education Young Elite Teacher Project.

Author contribution

Jing-shu TANG conducted the majority of biological experiments; Bing-xue XIE and Yu XUE performed the chemical synthesis; Xi-ling BIAN made the recordings of brain slices; Ning-ning WEI, Jing-heng ZHOU, and Yu-chen HAO performed some cell biology experiments; Jing-shu TANG and

Xi-ling BIAN analyzed the data; Jing-shu TANG drafted the manuscript; Gang LI, Liang-ren ZHANG, and Ke-wei WANG supervised the project and wrote and finalized the manuscript.
