TGF- β induces apoptosis in human B cells by transcriptional regulation of BIK and BCL-X_L

Transforming growth factor- β (TGF- β) potently induces apoptosis in Burkitt's lymphoma (BL) cell lines and in explanted primary human B lymphocytes. The physiological relevance and mechanism of TGF- β -mediated apoptosis induction in these cells remains to be determined. Here we demonstrate the requirement for TGF- β -mediated regulation of BIK and BCL-X_L to activate an intrinsic apoptotic pathway in centroblastic BL cells. TGF- β directly induced transcription of BIK and a consensus Smad-binding element identified in the *BIK* promoter recruits TGF- β -activated Smad transcription factor complexes *in vivo*. TGF- β also transcriptionally repressed expression of the apoptosis inhibitor BCL-X_L. Inhibition of BCL-X_L sensitised BL cells to TGF- β -induced apoptosis whereas overexpression of BCL-X_L or suppression of BIK by shRNA, diminished TGF- β -induced apoptosis. BIK and BCL-X_L were also identified as TGF- β target genes in purified normal human centroblast B cells and immunohistochemical analyses of tonsil tissue revealed widespread TGF- β receptor-regulated Smad activation and a focal pattern of BIK expression. Furthermore, using a selective inhibitor of the TGF- β receptor we provide evidence that autocrine TGF- β signalling through ALK5 contributes to the default apoptotic programme in normal human centroblasts undergoing spontaneous apoptosis. Our data suggests that TGF- β may act as a physiological mediator of human germinal centre homeostasis by regulation of BIK and BCL-X_L.

Cell Death and Differentiation (2009) 16, 593–602; doi:10.1038/cdd.2008.183; published online 9 January 2009

Transforming growth factor- β (TGF- β) is the prototypical member of a superfamily of pleiotropic cytokines, which regulate a multitude of biological processes including tissue homeostasis, angiogenesis, migration and differentiation. TGF- β signals by activation of a heterooligomeric receptor complex consisting of the type II receptor, TGF- β -RII and the type I receptor ALK5. These receptors activate a diverse range of intracellular signal transduction pathways including the canonical Smad pathway. The receptor-associated Smads 2 and 3 (R-Smads), are directly phosphorylated on their carboxy termini by the serine/threonine kinase domain of ALK5. Following phosphorylation the R-Smads heterooligomerise with the co-Smad, Smad4 and accumulate in the nucleus where in conjunction with a number of cofactors they regulate target gene expression.¹

TGF- β acts as a potent immunosuppressor by regulating the proliferation and survival of many cells of the immune system. Part of the homeostatic function of TGF- β is the cell type-specific induction of apoptosis, which occurs in several cell types including B cells.² Gene ablation studies in mice have indicated that TGF- β signalling affects B cells at all stages of development and is critical for secreted IgA responses.³ The observation that many lymphomas (including those derived from germinal centre (GC) B cells

undergoing differentiation) have defective TGF- β signalling pathways^{4,5} suggests that disruption of TGF- β apoptotic signalling in human B cells may contribute to lymphomagenesis.

GCs are the main sites for generating high-affinity antibody responses through repeated rounds of selection by apoptotic elimination of unwanted B cells. Activated B cells entering GCs undergo a process where immunoglobulin genes are altered by somatic hypermutation. Overtime, cells carrying mutated receptors with the highest affinity for foreign antigen outcompete others for limiting amounts of antigen and survival signals provided by T-cell help, so ensuring their continued survival and differentiation.⁶ At present, cell death at this site is generally thought to occur by Fas-dependent apoptosis (required for deletion of cells carrying low-affinity mutated immunoglobulins⁷). In addition, B-cell receptor (BCR) ligation in the absence of costimulatory receptor–ligand interactions is important for deletion of autoreactive B cells. In this context, Fas-mediated apoptosis is inhibited by cFLIP_L induced by survival signals from CD40 and BCR ligation. In the absence of these signals (e.g. during *in vitro* culture) cFLIP is rapidly degraded leading to spontaneous apoptosis,⁸ a process known as 'death by neglect'. GC B cells are therefore primed to die and require continued environmental cues for survival.

Signalling by CD40 and the BCR may help to render B cells 'Fas-resistant' by induction of the prosurvival BCL-2 homologue, BCL-X_L, although there are conflicting reports of its involvement in Fas-mediated cell death.⁹ It is likely, however, that BCL-X_L or BCL-2 expression induced by survival signals is required to antagonise a mitochondrial 'intrinsic' apoptosis pathway activated by antigen-BCR interaction. BCR-mediated cell death correlates with induction of BIM,¹⁰ which is a member of the proapoptotic BCL-2 family of proteins that also includes BIK, NOXA, BAD, BID, BMF and PUMA. These proteins antagonise the function of BCL-2 and its pro-survival homologues (BCL-X_L, BCL-w, MCL-1 and A1¹¹) resulting in activation of BAX and BAK. Once activated, BAX and BAK permeabilise the mitochondrial outer membrane¹² to release apoptogenic factors including cytochrome *c*, which complexes with APAF1 and procaspase-9 to form the apoptosome. Knockout mouse studies have implicated several proapoptotic components of this pathway in B-cell homeostasis.¹⁰

Previous findings suggest that TGF- β -mediated apoptosis may also be involved in normal human GC B-cell homeostasis. For example, we and others have shown that some Burkitt's lymphoma (BL) cell lines (which derive from B cells differentiating within GCs) are highly sensitive to TGF- β -induced apoptosis.^{5,13,14} Exogenous TGF- β also enhances apoptosis of primary explanted human and murine B lymphocytes.³ However, the physiological role of TGF- β signalling in GC reactions, the cell types within this compartment which die in response to TGF- β , and the effector mechanisms TGF- β employs to induce apoptosis remain to be elucidated.

Here we demonstrate that TGF- β contributes to 'death by neglect' by regulating an intrinsic apoptotic pathway in human centroblastic B cells. TGF- β impacts on apoptosis regulators upstream of BAX and BAK, by inducing the proapoptotic BH3-only protein BIK and downregulating BCL-X_L. These changes occurred both in BL cell lines and in their normal GC counterparts (centroblasts). Blocking the TGF- β -induced intrinsic pathway in primary human centroblasts provided cells with a survival advantage during spontaneous apoptosis. Our findings identify autocrine TGF- β signalling as a physiological regulator of a default mitochondrial apoptotic pathway in human B cells, and identify a novel function for BIK in B-cell homeostasis.

Results

Engagement of the intrinsic mitochondrial apoptosis pathway by TGF- β . To determine how TGF- β regulates apoptosis in centroblastic BL cells, we studied the response of a panel of BL cell lines to exogenous TGF- β . Ramos, BL2 and BL40 cells died following TGF- β addition shown by cleavage of the caspase substrate PARP, however, CA46 cells showed no PARP cleavage despite having an intact TGF- β signalling pathway (measured by phosphorylation of Smad2; Figure 1a).

We next analysed mitochondrial membrane integrity in apoptotic BL cells to determine whether the intrinsic pathway was activated by TGF- β . The gradual loss of the mitochondrial stain tetramethylrhodamine ethyl ester (TMRE) during 48 h

Figure 1 TGF- β activates an intrinsic apoptotic programme in centroblastic BL cells. (a) Western blot analysis of apoptosis (cleavage of the caspase substrate PARP) and TGF- β signalling (pSmad2) in a panel of BL cell lines treated with 1 ng/ml TGF- β for the times indicated. (b) Loss of mitochondrial inner membrane potential ($\Delta\Psi$ m) during TGF- β -induced apoptosis of Ramos cells shown by reduced mean fluorescence of cells labelled with the mitochondrial stain tetramethylrhodamine ethyl ester (TMRE). Cells were untreated (dash), labelled with TMRE alone (solid) or labelled with TMRE and treated with TGF- β (dotted). Cells were also treated with cyanide-m-chlorophenylhydrazine (CCCP; thick solid) to cause complete membrane depolarisation and serve as a positive control for $\Delta\Psi$ m. Cells were treated for the times indicated on each histogram and were analysed by flow cytometry

treatment of BL cells is consistent with involvement of the intrinsic mitochondrial pathway in TGF- β -induced apoptosis of BL cells (Figure 1b).

TGF- β regulates multiple BCL-2 family members. Induction of the intrinsic apoptosis pathway requires activation of BAX/BAK, which in turn is controlled by other members of the BCL-2 family. We therefore screened for transcriptional changes in BCL-2 family members during TGF- β -induced apoptosis. Multiprobe RNase protection assays (RPAs) demonstrated that TGF- β addition caused a rapid increase in transcripts of the proapoptotic BH3-only protein BIK in BL2 cells (Figure 2a) and in Ramos and CA46 BL cells (Supplementary Figure 1a). Elevated *BIK* expression in CA46 cells was initially surprising, as CA46 cells do not apoptose in response to TGF- β (Figure 1a; Inman and Allday⁵), however, further investigation confirmed previous reports¹⁵ that CA46 cells lack the mitochondrial membrane protein BAX (Supplementary Figure 1b) required for intrinsic apoptosis.

Figure 2 TGF- β -induced apoptosis in BL cells is associated with induction of BIK and downregulation of BCL-X_L. (a) Analysis of transcripts encoding BCL-2 family members by multiprobe RNase protection assay (RPA) following TGF- β treatment of BL2 cells. Total RNA from untreated or TGF- β treated cells was analysed during a 6 h time course. Lanes corresponding to yeast negative control RNA (Y), undigested probe (P) and ³²P-labelled pBR322 size markers (M) are shown. Sizes of the probe template set are also indicated. Confirmation of BIK induction (b) and BCL-X_L downregulation (c) by western blot analysis of RIPA lysates prepared from untreated and TGF- β (1 ng/ml) treated BL cell lines. BIM_{EL} expression was also measured and Smad2/3 levels are shown as a loading control. TGF- β signalling was analysed by western blotting for phosphorylation of Smad3 (p-Smad3). Actin blots are shown as a loading control

As well as inducing *BIK*, TGF- β treatment also rapidly decreased RNA expression of *BCL-X_L* in BL2 (Figure 2a), Ramos and CA46 cells (Supplementary Figure 1c). These effects were mirrored at the level of protein expression (Figure 2b and c), although the kinetics of BIK induction were more rapid than loss of BCL-X_L expression. No induction of BIM (a known TGF- β target gene^{16,17}) was observed (Figure 2b and Supplementary Figure 2a and b). BL2 cells lacked BIM expression altogether, but died efficiently upon exposure to TGF- β , indicating that BIM is unlikely to mediate the apoptotic response in the BL cell lines studied. In addition, we observed no change in MCL-1 levels or in BID expression or cleavage to the proapoptotic 15 kDa form, tBid (Supplementary Figure 2b). TGF- β -mediated apoptosis in BL cells therefore correlated primarily with effects on BIK and BCL-X_L.

To address whether these events are critical for apoptosis, we obtained BL cells stably overexpressing BCL-X_L.¹⁸ Elevated levels of BCL-X_L expression in the stably transfected cells (maintained throughout exposure to TGF- β) reduced the proportion of cells containing active caspase-3 (Figure 3a) and reduced cleavage of PARP induced by TGF- β (Figure 3b). Increased BCL-X_L expression therefore largely protected BL cells from TGF- β -mediated apoptosis thus confirming the involvement of mitochondria in the response. To investigate further whether BCL-X_L is critical for BL cell survival, we used an inhibitor to block the function of endogenous BCL-X_L. BH3i-2' inhibits BCL-2 and BCL-X_L by binding to their BH3-binding pocket.¹⁹ As BL2, Ramos and BL40 cell lines express BCL-X_L but lack BCL-2 protein expression (Figure 3c) we used BH3i-2' as a selective inhibitor of BCL-X_L in BL cells. All three cell lines apoptosed upon treatment with 30 μ M BH3i-2'. BL2 cells, which express a lower amount of BCL-X_L than either Ramos or BL40, were

sensitive to 5 μ M of the inhibitor (Figure 3d). Significantly, we were able to sensitise BL cells to TGF- β -induced apoptosis using low dose BCL-X_L inhibitor (5 μ M; Figure 3e). Apoptosis induction was greater following combined treatment than was observed with either TGF- β or the BCL-X_L inhibitor alone. The synergistic apoptotic response demonstrates that BCL-X_L regulation is an important factor in TGF- β -induced apoptosis in BL cells.

To test whether BIK induction is also required for optimal induction of apoptosis, we used a stable shRNA knockdown approach. Nonsilencing control and BIK shRNA retroviral vectors were generated to establish stable Ramos cell lines. qRT-PCR analysis revealed BIK shRNAs reduced expression to below basal levels in comparison with the nonsilencing vector (Figure 3f). Importantly, BIK knockdown resulted in a substantial reduction in TGF- β -mediated apoptosis (Figure 3g) without affecting TGF- β signalling (data not shown). Taken together, these findings reveal that the levels of BIK and BCL-X_L play a critical role in regulating TGF- β -dependent apoptosis in centroblastic BL cells.

BIK and BCL-X_L are direct and indirect TGF- β target genes. We next investigated the mechanism of TGF- β regulation of BCL-2 family members firstly by testing whether *BCL-X_L* and *BIK* are immediate early targets of TGF- β signalling. RPA analysis showed that repression of *BCL-X_L* required protein synthesis because pretreatment of cells with cycloheximide and anisomycin prevented the decrease in BCL-X_L RNA levels (Figure 4a). Induction of *BIK*, however, still occurred under these conditions but was completely blocked by inhibiting transcription with actinomycin D (Figure 4a and b) demonstrating that *BIK* is a direct transcriptional target of TGF- β signalling.

Figure 3 Regulation of BCL-X_L and BIK are critical for optimal TGF- β -mediated apoptosis. (a) Flow cytometry analysis of active caspase-3 positive cells (mean $\pm$ S.D., $n = 3$) induced by 24 h TGF- β treatment of L3055 BL cells and BCL-X_L stable transfectants. (b) Western blot analysis of RIPA extracts from L3055 BL cells and BCL-X_L stable transfectants after 48 h TGF- β treatment for PARP cleavage, BCL-X_L and phospho-Smad2 (p-Smad2). (c) Western blot analysis of 50 μ g RIPA extracts from untreated BL cells as indicated. Expression levels of BCL-X_L and BCL-2 in each cell line are shown. A western blot for actin is included as a loading control. (d) BL2, Ramos and BL40 cells were seeded overnight at 5×10^5 per ml and then treated for 48 h with the BCL-X_L inhibitor BH3i-2' (Calbiochem) as indicated. Apoptosis induction was determined by PI staining and flow cytometry (mean $\pm$ S.D., sub-G1 DNA content ($n = 3$)). (e) Ramos cells were left untreated or treated for 48 h with TGF- β in the presence or absence of low dose BH3i-2' (5 μ M). Apoptosis induction was determined by PI staining and flow cytometry (mean $\pm$ S.D., sub-G1 DNA content ($n = 3$)). (f) Independent stable cell lines (labelled 1 and 2) expressing nonsilencing (NS) and shRNAs targeted against Bik (Bik#1 and Bik#2) were generated by retroviral infection of Ramos BL cells. Quantitative real-time PCR (qRT-PCR) was used to demonstrate knockdown of *BIK* in stable Ramos BL cells. Mean relative amounts of *BIK* RNA are expressed after normalisation to 18s rRNA levels. (g) Determination of apoptosis (mean $\pm$ S.D., sub-G1 DNA content ($n = 3$)) by PI staining and flow cytometry following TGF- β treatment of cell lines described in (f)

The control of BCL-X_L transcription is complex, involving multiple promoters whose activity appears to be cell type and context dependent.²⁰ As the histone deacetylases (HDACs)-4 and 5 can be involved in repression of promoters by TGF- β ,²¹ we treated BL cells with an inhibitor of class I and class II HDACs, Trichostatin A (TSA), to gain insight into the possible mechanism of repression of BCL-X_L. As expected, TGF- β treatment for 8 h decreased the amount of BCL-X_L RNA expressed in both BL2 and BL40 cells. TSA pretreatment of BL cells to inhibit HDAC function, completely blocked the

ability of TGF- β to repress BCL-X_L transcription (Figure 4c) without affecting TGF- β signalling (Figure 4d). In fact, loss of HDAC function switched the response to TGF- β from one of repression to one of activation (in agreement with previous studies of the osteocalcin promoter).²¹ TGF- β regulation of BCL-X_L transcription may therefore involve chromatin remodelling through the recruitment of repressor complexes containing class I or II HDACs.

Our studies indicate that *BIK* is an immediate early target of TGF- β signalling in BL cells, and therefore is likely to be

Figure 4 TGF- β directly regulates *BIK* transcription and induces recruitment of activated Smad complexes to the BIK promoter. (a) RPAs for *BIK* and *BCL-X_L* expression in cells treated with or without TGF- β and the protein synthesis inhibitors cycloheximide and anisomycin (C + A) as indicated. Time points -2 and 0 are samples harvested before and after inhibitor treatment, respectively. TGF- β was added at 0 h. (b) RPA for *BIK* and the loading control GAPDH following TGF- β treatment of BL cells pretreated for 1 h with or without the transcription inhibitor actinomycin D (ActD). Time points -1 and 0 are samples harvested before and after inhibitor treatment, respectively. TGF- β was added at 0 h. M, P and Y are as described in Figure 2. (c) Real-time qRT-PCR carried out on RNA isolated from BL cell lines treated with TGF- β in the presence or absence of the HDAC inhibitor TSA. Shown is the mean $\pm$ S.D. amount of RNA normalised to 18s levels and relative to TGF- β untreated samples. (d) Western blot analysis of 50 μ g RIPA extracts from BL cells treated with and without TGF- β in the presence or absence of TSA as indicated. TGF- β signalling was analysed by western blotting for phosphorylation of Smads. A western blot for total Smad2/3 is included as a loading control. (e) Potential Smad-binding regions (SBRs) within the human *BIK* promoter. Arrows indicate positions of PCR primers used in ChIP assays shown in (f). (f) ChIP assay for Smad recruitment to the endogenous BIK promoter in BL cells cultured with and without TGF- β for 1 h. Input lanes are from 10% of samples used in the IPs performed with control IgG, Smad3 and Smad4 antibodies. (g) Sequence of ds oligos used in EMSAs shown in (h) containing the potential wild type and mutant SBR2 (mSBR2). SBE sequences are shown in bold. (h) EMSA of CA46 nuclear extracts treated with and without TGF- β for 1 h as indicated and incubated with wild-type SBR1 and SBR2 and mSBR2. TGF- β inducible and antibody supershifted complexes are shown (arrowed)

activated by Smad complexes. Smad-binding regions (SBRs) often contain two copies of the Smad-binding element (SBE) sequence 5'-GTCT-3' or its reverse complement 5'-AGAC-3'.²² We identified two potential SBRs approximately 1.1 kb upstream of the *BIK* transcription start site (Figure 4e). Chromatin immunoprecipitation (ChIP) analysis using primers spanning this region demonstrated the TGF- β -dependent recruitment of Smads 3 and 4 to the endogenous *BIK*

promoter in BL cells *in vivo* (Figure 4f). Radiolabelled dsDNA probes of SBR1 and SBR2 were prepared (wild-type and mutant SBR2 sequences are shown in Figure 4g) and used in electrophoretic mobility-shift assays (EMSA) to determine which SBR in the region assayed by ChIP could bind Smad complexes *in vitro*. SBR2 bound a TGF- β inducible complex which could be supershifted with Smad3 and Smad4 antibodies (Figure 4h). SBR1 and a mutated form of SBR2,

which abrogates the consensus SBEs, were unable to bind Smad3/4 complexes (Figure 4h). These data suggest that TGF- β activates *B/K* by direct binding of transcriptionally active Smad3/4 complexes to the SBR2 sequence within the promoter.

Autocrine TGF- β signalling in primary human centroblasts. BLs originate within GCs and phenotypically resemble centroblasts. Exogenously added TGF- β enhances apoptosis of GC B cells *in vitro*²³ but the mechanism of induction and what contribution TGF- β makes to normal GC development is not fully understood. Having determined how TGF- β induces apoptosis in BL cell lines, we studied whether these responses occur in primary human tonsil cells. In addition to studying the effects of exogenously added TGF- β , we used SB-431542, a selective inhibitor of ALK5,²⁴ to block endogenous TGF- β signalling. Total mononuclear cells (TMCs), purified CD77+ve centroblasts (isolated by positive selection) and TMCs depleted of CD77+ve cells responded to exogenous TGF- β as shown by increased Smad2 and Smad3 phosphorylation (Supplementary Figure 3a). Interestingly, active Smad2 was also detected in untreated cells cultured for 1 h in serum-free medium. This endogenous signalling was completely ablated by treatment with SB-431542 (Supplementary Figure 3a), which suggests that, in the absence of external sources of cytokine, autocrine TGF- β signalling by the ALK5 receptor occurs in GC B cells and isolated centroblasts. Consistent with this, we found

that centroblasts express TGF- β 1 mRNA (Supplementary Figure 3b).

ALK5 inhibition enhances centroblast survival. As centroblasts exhibit endogenous TGF- β signalling and respond to increased doses of TGF- β , we examined the biological consequences of signalling. First we analysed by flow cytometry (FCM) the survival of centroblasts (CD38/CD77 double positive cells) in populations of TMCs cultured with either TGF- β or SB-431542. During *in vitro* culture the percentage of double positive cells decreased. This process was enhanced by addition of TGF- β and partially suppressed by treatment with SB-431542 relative to controls (Figure 5a). Similar results were obtained with CD77 staining alone (Figure 5b), enabling the use of CD77+ve selection purification techniques to examine further the role of TGF- β signalling in these cells.

Culture of purified centroblasts resulted in spontaneous apoptosis shown by PARP cleavage (Figure 5c, lane 2). Treatment with the mitogen, PMA, partially rescued centroblasts from spontaneous apoptosis but was unable to overcome cell death induced by addition of TGF- β (Supplementary Figures 4a and 4b). Interestingly, when centroblasts were cultured with SB-431542 we were able to consistently prolong cell survival shown by a reduced PARP cleavage (Figure 5c). In addition, we detected fewer centroblasts containing active caspase-3 following isolation and culture with the ALK5 inhibitor (Figure 5d). No PARP cleavage was evident in any CD77 depleted TMCs (Supplementary Figure 4a) despite

Figure 5 Autocrine TGF- β signalling contributes to spontaneous centroblast apoptosis. Flow cytometry analysis of centroblasts in preparations of explanted normal human total mononuclear cells (TMCs) showing the percent survival of CD77/CD38+ve cells (a) and the percentage of anti-CD77-FITC stained cells remaining after 24 and 48 h *in vitro* culture of TMCs (b) with either exogenous TGF- β or an inhibitor of TGF- β signalling (SB-431542, 10 μ M) or solvent control (DMSO). (c) Western blot analysis for PARP cleavage and actin of extracts from 1×10^5 purified centroblasts incubated for 36 h with TGF- β , SB-431542 or DMSO solvent control. Actin levels are shown as a loading control. (d) Percent of active caspase-3 negative cells (mean $\pm$ S.D., $n = 3$) determined by PhiPhiLux (G1D2) fluorescent caspase substrate and flow cytometry in purified centroblasts treated with DMSO (–) or SB-431542 for the indicated times

apoptosis taking place in whole TMC cultures (data not shown). Thus, we conclude that CD77 + ve cells are the only cell type present in TMCs that apoptose in response to TGF- β and that blocking endogenous signalling with a selective inhibitor of ALK5 provides these cells with a survival advantage following withdrawal of environmental cues.

TGF- β regulates BIK and BCL-X_L in primary human centroblasts. To assess whether apoptosis induction is mechanistically similar in both BL cell lines and their normal GC counterparts we analysed whether TGF- β signalling can be detected in intact GCs, and whether BIK and BCL-X_L are also TGF- β target genes in primary human centroblasts. Formalin-fixed paraffin-embedded tonsil tissues were stained for phosphorylated Smad2 and Ki67, a marker of proliferation (Figure 6a). Ki67 highlighted dark and light zones of the GC. Phosphorylated Smad2 was readily detected within both zones as well as in the surrounding mantle zone. A more restricted expression pattern of BIK was detected within the dark and light zones of GCs.

RPA analysis demonstrated that purified CD77 + ve cells express BCL-X_L, and high levels of BIK RNA (Supplementary Figure 5). BCL-2 was poorly expressed confirming previous observations.²⁵ Western blotting of lysates from total mononuclear cells (TMCs), purified CD77 + ve cells and TMCs depleted of centroblasts revealed that whereas BIK protein could only be detected very weakly in TMCs, purified CD77 + ve cells were strongly positive for BIK, demonstrating that BIK expression is restricted to centroblasts (Figure 6b). qRT-PCR analysis carried out on purified centroblasts treated with the pancaspase inhibitor ZVAD to inhibit apoptosis showed that BIK and BCL-X_L RNA levels were significantly increased and reduced, respectively, by TGF- β addition whereas the levels of BIM were unchanged (Figure 6c). Taken together, the findings reveal that TGF- β signalling is widespread during GC reactions and that the effectors of apoptotic responses induced by TGF- β in BL cell lines and primary centroblasts are identical.

Discussion

This study reveals that TGF- β mediates apoptosis in GC derived B cells by a mitochondrial intrinsic pathway (Figure 1b). The mechanism of apoptosis induction involved transcriptional regulation of the BCL-2 family members, BIK and BCL-X_L (Figures 2 and 4). In addition, we provide the first evidence of a causal relationship between BIK and TGF- β -induced apoptosis (Figure 3g) and show that BCL-X_L is important for BL cell survival and the outcome of their response to TGF- β signalling. Overall our data indicates that the relative levels of BIK and BCL-X_L dictates the apoptotic response of centroblastic cells to TGF- β . We might therefore also predict that cross talk between the TGF- β and BCR receptor signalling pathways is likely, as BIK (as well as BIM) may be regulated by BCR ligation.²⁶

Upon induction, BH3-only proteins like BIK induce apoptosis by binding directly to prosurvival BCL-2 family members, which constrain BAX and BAK activation. BIK has been described as promoting cell death by sequestering BCL-2 and BCL-X_L²⁷ and antagonising MCL-1 and BCL-X_L during

Figure 6 TGF- β -mediated regulation of BIK and BCL-X_L in primary human centroblasts. (a) Sections of formalin-fixed paraffin-embedded human tonsil tissue were stained with antibodies as indicated and counterstained with haematoxylin. Scale bars represent 200 μ m. (b) Western blot analysis of BIK expression in TMCs, TMCs depleted of centroblasts (CD77 depleted) and isolated centroblasts (purified CD77). A western blot for actin is included as a loading control. (c) Real-time qRT-PCR carried out on RNA isolated from purified centroblasts treated with zVAD-fmk and -/+ TGF- β for 2–4 h (BIK and BIM) or 16–24 h (BCL-X_L). The mean fold changes in relative RNA expression compared to untreated controls are shown. Statistical analysis was carried out using paired *t*-tests (*n* = 3). Statistically significant (*P*) values of < 0.005 (**) are indicated

apoptosis caused by protein synthesis inhibition.²⁸ As centroblastic cells express very little BCL-2 (Supplementary Figure 5; Klein *et al.*²⁵) induction of BIK in this cell type is more likely to antagonise the function of BCL-X_L and/or MCL-1. Indeed, maintaining BCL-X_L protein levels in BL cell lines partially overcame the apoptotic effects of TGF- β (Figure 3a

and b), whereas inhibiting BCL-X_L function sensitised BL cells to the effects of TGF- β (Figure 3e). Given the important role of BCL-X_L in the TGF- β -mediated apoptotic response, it is possible that the defect in GC apoptosis seen in *Bcl-X_L* transgenic mice, which results in 'relaxed' negative selection and impaired affinity maturation,²⁹ could be a consequence of a defective default TGF- β apoptosis programme.

BIK is transcriptionally regulated by p53³⁰ and E2F-1,^{31,32} and we now identify BIK as a novel TGF- β target gene in human B cells via Smad recruitment to the promoter. Our conclusion that BIK is involved in B-cell homeostasis is supported by the observations that mice with a heritable defect resulting in elevated levels of BIK RNA, have higher levels of apoptosis in splenic B cells, and normal B-cell development can be restored by BCL-X_L overexpression.³³ On the other hand, *Bik*^{-/-} mice appear quite normal and their B cells are still sensitive to spontaneous apoptosis.³⁴ To reconcile these observations, it is possible that murine and human B cells respond differently in some respects to TGF- β signalling. Significantly, the SBR recruiting Smads to the endogenous human *BIK* promoter (shown in Figure 4e and f) is not conserved in the mouse or rat (data not shown), indicating that BIK is unlikely to be involved in TGF- β -regulated GC homeostasis in mice.

Using a selective inhibitor of TGF- β receptor function, we also show that TGF- β signalling through ALK5 is an important physiological modulator of apoptosis of human centroblasts in the absence of survival stimuli (Figure 5). It is possible that exogenous sources of TGF- β may contribute to the regulation of centroblasts *in vivo*, nevertheless, purified centroblasts exhibited phosphorylation of Smads in the absence of serum and express TGF- β 1 RNA (Supplementary Figure 3b), suggesting that treatment of the cells with SB-431542 inhibits a functional autocrine TGF- β signalling pathway.

Thus far, we have not yet fully elucidated the mechanism of BCL-X_L repression. Transcriptional regulation of BCL-X_L is complex, involving numerous different transcription factors and three distinct promoters regulating initiation at the 5' end of two noncoding exons, 1A and 1B, and at the beginning of exon II.²⁰ One possible mechanism of BCL-X_L regulation by TGF- β is through increased expression of the TGF- β -induced early genes 1 and 2 (*TIEG1* and *TIEG2*), which regulate BCL-X_L levels in oligodendroglial precursor cells.³⁵ *TIEG1* was undetectable in BL cells by western blotting, and whereas *TIEG2* was expressed its levels were unaltered by TGF- β (LS, unpublished observations). It therefore seems unlikely that induction of either *TIEG1* or *2* is involved in BCL-X_L regulation in BL cells. However, our data suggests that (as in the case of TGF- β -mediated repression of osteocalcin) chromatin remodelling in the form of recruitment of HDAC-containing repressor complexes may be involved. Studies are currently underway to characterise the mechanism of repression further.

A model of centroblast death. Overall our data provides evidence for a revised model of centroblast apoptosis (Figure 7) to include the novel involvement of TGF- β in regulating an intrinsic apoptosis pathway. We propose that autocrine TGF- β signalling through ALK5 contributes to the default apoptotic state apparent in centroblasts lacking

Figure 7 Model of centroblastic cell apoptosis pathways. The contribution of TGF- β signalling to regulation of BCL-2 family members is included alongside known apoptosis pathways functional in germinal centres. The three separate apoptosis pathways converge to regulate death of human centroblasts. Fas signalling activates the extrinsic caspase-8/caspase-3 cascade whereas TGF- β signalling by its receptor complex represses the prosurvival factor BCL-X_L and induces BIK to activate the intrinsic pathway. Fas and TGF- β signalling contribute to the default apoptotic state of 'death by neglect' whereas B-cell receptor signalling also activates the mitochondrial apoptosis pathway in cells lacking environmental survival cues. Loss of TGF- β signalling through inhibition of TGF- β receptor signalling by SB-431542 would reduce the amount of caspase-3 activation and raise the threshold for apoptosis induction. The model highlights the requirement for maintenance of cFLIP and BCL-X_L levels for cells to survive during germinal centre reactions

survival stimuli. Parallel Fas (extrinsic) and TGF- β (intrinsic) pathways converge to regulate death by neglect, via caspase-8 and caspase-9, respectively. In line with this, chemical inhibition of caspase-9 activity in explanted GC B cells enhances their survival.³⁶ Our data implies that survival signals provided during affinity maturation must overcome both pathways.

Our data also suggests that defective TGF- β signalling would provide GC B cells with a survival advantage during selection. Indeed many lymphomas of B-cell origin have aberrant TGF- β signalling or defects in downstream components of the signalling pathway⁴ while mutations in *BIK* have been reported in B-cell lymphomas of GC origin.³⁷ We hypothesise therefore that disruption of the TGF- β -regulated apoptotic programme in human B cells may contribute to lymphomagenesis and/or autoimmune pathology.

Materials and Methods

Cell lines and reagents. BL cell lines were maintained in RPMI-1640 (Gibco-BRL) supplemented with 5–10% (v/v) heat-inactivated FCS, 2 mM/ml glutamine and antibiotics. Cells were treated as required with 1 ng/ml TGF- β 1 (Peprotech), 50 μ M zVAD-fmk (Calbiochem) and 10 μ M SB-431542 (Tocris). Protein synthesis inhibition was carried out by preincubation for 2 h with 50 μ g/ml cycloheximide and 100 μ M anisomycin (Sigma). Inhibition of transcription was carried out by pretreatment of cells for 1 h with 2.5 μ g/ml actinomycin D (Sigma). The inhibitor of BCL-X_L function (BH3i-2') was purchased from Calbiochem and reconstituted in DMSO at a concentration of 15 mM. For inhibition of HDAC function cells were pretreated for 15 min with 330 nM TSA (Sigma).

Isolation of centroblasts. Ethical permission was obtained for collection and use of normal tonsil tissue (confirmed on histology) from the Southern General

Hospital Ethics Committee (reference EC/04/S/06) and registered with the Research and Design Office (reference R040016) following routine tonsillectomy. Total mononuclear cells (TMCs) were isolated by Ficoll density gradient. CD77 + ve cells were purified using rat anti-human CD77 (Immunotech) followed by mouse anti-rat IgM (BD Biosciences) and rat anti-mouse IgG1 microbeads (Miltenyi Biotech). Cells were purified using an AutoMacs (Miltenyi Biotech) and were cultured at 37°C in RPMI plus 15% FCS at 1×10^7 per ml.

Immunoblotting and antibodies. RIPA lysates were analysed by SDS-PAGE. Antibodies used in western blotting were mouse monoclonals against PARP (BD Biosciences), BIK (FL-160, Santa Cruz), Smad2/3 (BD Biosciences) and actin (Sigma) and rabbit polyclonal antibodies against phospho-Smad 2 (ser465/476), phospho-Smad 3 (ser 433/435), BID and BCL-X_L (Cell Signaling), MCL-1 (Santa Cruz) and BIM (Chemicon). Secondary HRP-conjugated antibodies were obtained from Dako. Bound immunocomplexes were detected by enhanced chemiluminescence (Amersham). Prestained protein marker sizes are shown on each gel.

Analysis of cell surface markers by flow cytometry. A total of 1×10^6 cells in PBS/0.5% BSA were labelled on ice for 1 h with the appropriate concentration of antibody before being washed and analysed by FCM (BD FACScan or FACS Calibur). Antibodies used were PE-conjugated anti-CD38 and FITC-conjugated anti-CD77 (BD Biosciences). At least 10^4 events were acquired and analysed using CellQuest software. Analysis gates were set to include 1% of cells of an unstained or isotype matched control stained population.

Analysis of apoptosis by flow cytometry. Cells were fixed, labelled with propidium iodide (PI) and analysed by FCM for sub-2N DNA content, or analysed by measuring intracellular caspase-3 activity using fluorogenic peptide substrates of caspase-3 (PhiPhiLux, G1D2; Calbiochem) as recommended by the manufacturer. To monitor mitochondrial membrane potential, cells were incubated for 20 min in medium containing 40 nM of the mitochondrial stain TMRE (Molecular Probes). Treatment with cyanide-*m*-chlorophenylhydrazine induced complete mitochondrial membrane depolarisation as a positive control.

RNAse protection assay. Total cellular RNA was extracted using Trizol. RPA was carried out as described previously³⁸ using the hApo2b multiprobe template set (BD Biosciences Pharmingen).

Retroviral infection of BL cell lines. shRNA-mirs targeting BIK were generated using oligonucleotides described in supplementary text cloned into MSCV/LTRmiR30-PGΔRI (LMP; a kind gift of Ross Dickens and Scott Lowe).³⁹ Amphotropic retroviruses were generated as described in Supplementary materials and methods. BL cells, seeded at 5000 cells per well in 96-well plates, were infected with viral supernatants by centrifugation at 37°C 4000 $\times$ g for 1.5 h. Cells were incubated overnight before addition of growth medium containing 0.6 μ g/ml puromycin. Stable cell pools were analysed directly after outgrowth in selection medium.

qRT-PCR. Total cell RNA was isolated using Trizol as recommended by the manufacturer. cDNA and qRT-PCR reactions were prepared using SYBR green 2-step qRT-PCR kits (Finnzymes) and specific primers for each gene (Qiagen). Amplified products were analysed by Chromo4 continuous fluorescence detector and Opticon Monitor3 software. The relative amount of RNA for each gene is expressed after normalisation to the amount of 18S rRNA in each sample.

ChIP assay. CA46 cells (2×10^7) were treated with 1 ng/ml TGF- β for 1 h and fixed in 1% formaldehyde for 15 min. Samples were prepared as described in Supplementary text before analysis by PCR.

Immunohistochemistry. Sections (2 μ m) of formalin-fixed paraffin-embedded human tonsil tissue were stained with antibodies raised against Ki67, BIK or phospho-Smad 2 as described in Supplementary materials and methods.

EMSA. Band shifts were performed as described⁴⁰ using the ds oligos described in Supplementary materials and methods. A total of 5 μ g of nuclear extract derived from the appropriate cell type and condition was incubated with radiolabelled oligonucleotide probes. For supershifts, anti-Smad3 (Zymed) and anti-Smad4 (Santa Cruz) were also included.

Acknowledgements. We thank Colin Nixon for immunohistochemical staining; Brad Ozanne, John Wyke and Kevin Ryan for reviewing the article, Ulf Klein and Ricardo Dalla-Favera for protocols on centroblast isolation and Ross Dickens and Scott Lowe for retroviral shRNA-mir plasmids. LCS, DO'B, DD and GJL are supported by CRUK and an AICR fellowship to GJL. DI O'B and DD performed research, DS and LJC collected patient material, CDG supplied reagents, MJA designed initial research. LCS and GJL designed and performed research, analysed and interpreted data and drafted the article.
