Double-stranded RNA promotes CTL-independent tumor cytolysis mediated by CD11b⁺Ly6G⁺ intratumor myeloid cells through the TICAM-1 signaling pathway

Hiroaki Shime^{*1}, Misako Matsumoto¹ and Tsukasa Seya¹

PolyI:C, a synthetic double-stranded RNA analog, acts as an immune-enhancing adjuvant that regresses tumors in cytotoxic T lymphocyte (CTL)-dependent and CTL-independent manner, the latter of which remains largely unknown. Tumors contain CD11b⁺Ly6G⁺ cells, known as granulocytic myeloid-derived suppressor cells (G-MDSCs) or tumor-associated neutrophils (TANs) that play a critical role in tumor progression and development. Here, we demonstrate that CD11b⁺Ly6G⁺ cells respond to polyI:C and exhibit tumoricidal activity in an EL4 tumor implant model. PolyI:C-induced inhibition of tumor growth was attributed to caspase-8/3 cascade activation in tumor cells that occurred independently of CD8 α ⁺/CD103⁺ dendritic cells (DCs) and CTLs. CD11b⁺Ly6G⁺ cells was essential for the antitumor effect because depletion of CD11b⁺Ly6G⁺ cells totally abrogated tumor regression and caspase activation after polyI:C treatment. CD11b⁺Ly6G⁺ cells that had been activated with polyI:C showed cytotoxicity and inhibited tumor growth through the production of reactive oxygen species (ROS)/reactive nitrogen species (RNS). These responses were abolished in either Toll/interleukin-1 receptor domain-containing adaptor molecule-1 (TICAM-1)^{-/-} or interferon (IFN)- $\alpha\beta$ receptor 1 (IFNAR1)^{-/-} mice. Thus, our results suggest that polyI:C activates the TLR3/TICAM-1 and IFNAR signaling pathways in CD11b⁺Ly6G⁺ cells in tumors, thereby eliciting their antitumor activity, independent of those in CD8 α ⁺/CD103⁺ DCs that prime CTLs.

Cell Death and Differentiation (2017) 24, 385–396; doi:10.1038/cdd.2016.131; published online 11 November 2016

Immune cells are implicated in the regulation of tumor growth.^{1,2} Myeloid-derived cells, such as macrophages and dendritic cells (DCs), express Toll-like receptors (TLRs) and participate in the formation of tumor-progressive or tumor-suppressive microenvironments in response to pattern-recognition receptor (PRR) stimuli. Intratumor myeloid cells phagocytose tumor debris containing tumor-associated antigens (TAAs) to prime antigen-specific cytotoxic T lymphocytes (CTLs) together with released cytokines.² Although CTLs are critical for tumor regression, tumor cells do not always generate neoantigens or present TAAs.^{3,4} Even under the conditions where CTLs no longer participate in tumor elimination, TLR ligands often induce a tumor-regressive response. Therefore, a CTL-independent antitumor event occurs via stimulation of TLRs in tumor-associated myeloid cells during immunotherapy with TLR ligands. The mechanism of this antitumor response remains largely undetermined.

PolyI:C, a synthetic double-stranded RNA (dsRNA) analog, induces type-I interferon (IFN) production and fosters CD8 α ⁺/CD103⁺ DC maturation, leading to tumor growth inhibition mediated by natural killer (NK) cells and CTLs in mice.^{5,6} In either case, polyI:C activates TLR3 in endosomes.⁷ TLR3 activates Toll/interleukin-1 receptor domain-containing adaptor molecule-1 (TICAM-1) that evokes the production of type-I IFNs and proinflammatory cytokines.⁸ PolyI:C additionally

activates the melanoma differentiation-associated gene 5 (MDA5)-mitochondrial antiviral-signaling protein (MAVS) pathway that induces a systemic IFN/cytokine production.⁹ These pathways are conserved in most myeloid cells.

Myeloid-derived cells are abnormally accumulated in tumor-bearing hosts. CD11b⁺Ly6G⁺ cells represent a population of tumor-supporting myeloid cells in mice.¹⁰ They accumulate in tumors and blood/lymphoid organs and promote tumor growth, metastasis, angiogenesis, and immunosuppression.^{11–14} CD11b⁺Ly6G⁺ cells are identified as granulocytic myeloid-derived suppressor cells (G-MDSCs) or as tumor-associated neutrophils (TANs).¹⁰ G-MDSCs and TANs show morphological and functional similarities to neutrophils.¹⁵ In patients, neutrophil infiltration into a tumor is correlated with poor prognosis.^{16,17}

G-MDSCs preferentially produce reactive oxygen species/reactive nitrogen species (ROS/RNS) including hydrogen peroxide (H₂O₂) and peroxynitrite (PNT). PNT is responsible for the suppression of T cell-mediated antitumor immunity by G-MDSCs.^{18–21} Consequently, these suppression mechanisms enable tumor cells to escape tumor antigen-specific CTLs. However, emerging evidence has revealed that functionally polarized neutrophils induced by cytokines, chemokines, or growth factors inhibit tumor growth and metastasis.^{22–24} CD11b⁺Ly6G⁺ cells, therefore, have both a

positive and negative impact on tumor growth that can be determined by external stimuli. CD11b⁺Ly6G⁺ cells may act as a CTL-independent effector of tumor regression in response to TLR ligands.

Tumor growth can be altered by targeting immunosuppressive myeloid cells.²⁵ Administration of ligands for TLR3 or TLR9 induces a functional conversion of CD11b⁺Gr1⁺ MDSCs or CD11b⁺Ly6G⁺Ly6C^{high} monocytic MDSCs (M-MDSCs).^{26–28} We have previously demonstrated that a polyI:C-induced TLR3/TICAM-1 signal induces tumoricidal activity in tumor-associated macrophages (TAMs), leading to tumor growth inhibition in 3LL tumor-bearing mice.²⁹ In this study, using an EL4 tumor model, we found that CD11b⁺Ly6G⁺ cells inhibit tumor growth upon polyI:C treatment even if tumor cells are out of targets of CTL, NK, and M1 TAM-mediated cytotoxicity.

Results

Inhibition of tumor growth by polyI:C treatment through the TICAM-1 signaling pathway. The growth of EL4 tumors in mice was significantly retarded by polyI:C administration (Figure 1a). To analyze the host signaling pathway involved in this tumor growth inhibition, EL4 cells were implanted into mice deficient for TICAM-1 or MAVS that are downstream adapter molecules of TLR3 or MDA5, respectively. The polyI:C-induced inhibition of tumor growth was abrogated in TICAM-1^{−/−} but not MAVS^{−/−} mice (Figure 1a). PolyI:C induces type-I IFN production, and the inhibition of EL4 tumor growth was abrogated in IFNAR1^{−/−} mice. Thus, polyI:C treatment led to the inhibition of EL4 tumor growth via the TLR3/TICAM-1 and type-I IFN signaling pathways. EL4 cells express MHC class-I (H-2D^b and H-2K^b), CD3ε, CD28, PD-1, and PD-L1, but not MHC class-II (I-Ab), CD4, CD8, CD11b, CD11c, and CTLA-4 (Supplementary Table 1). EG7 cells expressing a model TAA (OVA protein) are a CTL-sensitive cell line derived from EL4 cells. However, polyI:C-induced inhibition of EL4 tumor growth was not abrogated by pretreatment of mice with antibodies (Abs) against CD8β, CD4, or NK1.1 (Figure 1b).

PolyI:C treatment robustly increased TUNEL (terminal deoxynucleotidyl transferase-mediated nick end labeling)-positive cells, suggesting that apoptosis or necrosis occurred in the tumor (Figure 1c). Cleaved caspase-3, an apoptosis marker,^{30,31} was increased throughout the tumors after polyI:C treatment; this effect was abrogated in TICAM-1^{−/−} and IFNAR1^{−/−}, but not MAVS^{−/−} mice (Figure 1d). Caspase-3 activation is induced by caspase-8, 9, or 12.³¹ Cleaved caspase-8 was increased in tumor at 7 and 18 h after polyI:C injection (Figures 1e and f). The full-length caspase-9 slightly decreased and the amount of full-length caspase-12 was unchanged. These data suggest that polyI:C treatment

induces apoptosis of EL4 tumor cells through the caspase-8/3 cascade, resulting in tumor growth inhibition. The TLR3/TICAM-1 pathway triggers apoptosis in cancer cells through caspase-8 activation.³² However, EL4 cells are insensitive to direct stimulation with polyI:C.³³

The polyI:C-induced caspase-3 activation in tumors occurred in Batf3^{−/−} mice that lack CD8α⁺/CD103⁺ DC subsets³⁴ (Supplementary Figure 1). Taken together, the CD8α⁺/CD103⁺ DC-mediated NK and CTL induction is unlikely involved in the inhibition of EL4 tumor growth. That is, previously unidentified cells and/or mechanisms could participate in the therapeutic potential of polyI:C in the EL4-implant model.

CD11b⁺Ly6G⁺ cells are essential for polyI:C-induced inhibition of EL4 tumor growth in mice. We ultimately found that depletion of Gr1⁺ cells abolished the polyI:C-induced inhibition of tumor growth (Figure 2a). Gr1 is a common epitope of both Ly6G and Ly6C that are highly expressed on G-MDSCs/TAN and M-MDSCs, respectively. Treatment of tumor-bearing mice with an Ly6G-specific Ab (1A8) almost completely abrogated both of the polyI:C-induced events: tumor growth inhibition and caspase-8/3 activation in tumors (Figures 2b and c). Ly6G⁺ cells coexpressed CD11b (Supplementary Figure 2). Hence, CD11b⁺Ly6G⁺ cells are responsible for the inhibition of EL4 tumor growth in polyI:C-treated mice.

PolyI:C-activated CD11b⁺Ly6G⁺ cells inhibit tumor growth. We analyzed the gene expression profile of CD11b⁺Ly6G⁺ cells isolated from tumor-bearing mice. IFN-α/β were upregulated in CD11b⁺Ly6G⁺ cells in response to 4 h of polyI:C treatment, an effect that was abrogated in TICAM-1^{−/−} CD11b⁺Ly6G⁺ cells, whereas mRNA expression of neither tumor-supporting factors such as arginase-1 (Arg-1) nor vascular endothelial growth factor A (VEGFA) were altered (Supplementary Figure 3a). Therefore, CD11b⁺Ly6G⁺ cells respond to polyI:C *in vivo* within 4 h to alter their function.

CD11b⁺Gr1⁺ cells isolated from tumor-bearing mice promote tumor growth when co-injected with tumor cell lines.^{35–37} Thus, we tested whether polyI:C-activated CD11b⁺Ly6G⁺ cells inhibited tumor growth. CD11b⁺Ly6G⁺ cells isolated from tumor-bearing mice pretreated with polyI:C or PBS (as a control) were mixed with EL4 cells and then implanted subcutaneously into tumor-free mice. When EL4 cells were co-implanted into mice with CD11b⁺Ly6G⁺ cells from PBS-treated tumor-bearing mice, the tumor growth rate was similar to that of EL4 cell-implanted mice (without CD11b⁺Ly6G⁺ cells) (Figure 2d, upper). In contrast, tumor growth was significantly delayed when EL4 cells

Figure 1 TICAM-1-dependent inhibition of tumor growth and caspase-8/3 activation in tumors. (a) Tumor growth in B6 WT, TICAM-1^{−/−}, or MAVS^{−/−} mice. PBS or polyI:C (100 μg) was injected s.c. as indicated by the arrows. (b) Tumor growth in B6 WT mice treated with anti-CD8β, anti-NK1.1, or anti-CD4 Abs. PBS/polyI:C or Ab was injected as indicated by the arrows or arrowheads, respectively. The results represent the mean ± S.D. (n = 3–5, **P < 0.005, n.s., not significant) (a and b). (c) TUNEL staining in tumors at 24 h after PBS or polyI:C (200 μg) injection (i.p.). (d) Caspase-3 activation in tumors implanted in WT, TICAM-1^{−/−}, MAVS^{−/−}, or IFNAR1^{−/−} mice at 18 h after polyI:C injection. Scale bars: 200 μm. (e and f) Western blot analysis of tumors isolated from mice at 18 h (e) or 7 h (f) after PBS or polyI:C (200 μg) injection. The intensity of the bands indicated by asterisks was quantified using ImageJ software (<http://rsb.info.nih.gov/ij/>) and normalized to GAPDH. All data are representative of at least two independent experiments

were co-implanted with CD11b⁺Ly6G⁺ cells from polyI:C-treated mice (Figure 2d, upper). Thus, polyI:C-activated CD11b⁺Ly6G⁺ cells are sufficient to inhibit tumor growth. In

contrast, CD11b⁺Ly6G⁺ cells isolated from tumor-bearing TICAM-1^{-/-} mice pretreated with polyI:C failed to inhibit tumor growth (Figure 2d, lower).

Figure 2 CD11b⁺Ly6G⁺ cells are essential and sufficient for the TICAM-1-induced antitumor effect. (a) Tumor growth of EL4 cells in an anti-Gr1 Ab-treated B6 WT mice. Abs were injected i.p. on days 7 and 11. PBS or polyI:C (100 μ g) was injected s.c. on days 8 and 12. (b) Tumor growth in isotype control Ab or anti-Ly6G Ab-treated B6 WT mice. Abs were injected i.p. on days 9 and 13. PBS or polyI:C (100 μ g) was injected s.c. on days 10 and 14. The results represent the mean $\pm$ S.D. ($n = 3-4$, $*P < 0.05$, n.s., not significant). (c) Western blot analysis of tumors isolated from Ly6G⁺ cell-depleted mice 18 h after injection of PBS or polyI:C (200 μ g). (d) CD11b⁺Ly6G⁺ cells (1×10^6) isolated from PBS or polyI:C-treated B6 WT or TICAM-1^{-/-} tumor-bearing mice were mixed with EL4 cells (5×10^5), and the mixture was injected s.c. into B6 WT mice on day 0 ($n = 4$, $*P < 0.05$). (e) Cytotoxic activity of CD11b⁺Ly6G⁺ cells isolated from the spleen of tumor-bearing WT or TICAM-1^{-/-} mice, 4 h after treatment with polyI:C (200 μ g). Data represent mean $\pm$ S.D. ($n = 3$, $**P < 0.005$). Data are representative of at least two independent experiments

We next asked whether CD11b⁺Ly6G⁺ cells in tumor-bearing mice directly killed EL4 cells. CD11b⁺Ly6G⁺ cells from polyI:C-treated tumor-bearing mice showed higher cytotoxic activity than CD11b⁺Ly6G⁺ cells from PBS-treated mice (Figure 2e, upper). CD11b⁺Ly6G⁺ cells isolated from TICAM-1^{-/-} mice did not show this activity (Figure 2e, lower).

TNF family receptors do not participate in the inhibition of EL4 tumor growth by polyI:C. Ligand stimulation of tumor necrosis factor (TNF) family receptors, such as TNF receptor-1 (TNFR1), receptors for TNF-related apoptosis-inducing ligand (TRAIL), or Fas induces apoptosis through the activation of caspase-8/3.³⁰ PolyI:C enhances the expression of ligands of the TNF receptor family in myeloid-derived cells. Therefore, we tested whether those ligands are involved in the antitumor effect of polyI:C. TNF- α , a TNFR1 ligand, did not participate in the polyI:C-induced caspase-3 activation in EL4 tumors, as determined from TNF α ^{-/-} mice (Supplementary Figure 4a). TNF- α does not induce cell death of EL4 cells.²⁹ We observed that *in vivo* and *in vitro* polyI:C

treatment increased mRNA expression of TRAIL in CD11b⁺Ly6G⁺ cells (Supplementary Figure 4b). TRAIL induces apoptosis of tumor cells such as C1498 cells via DR4/5 receptor stimulation.³⁰ DR5 expression was observed on the surface of EL4 cells (Supplementary Figure 4c). Recombinant TRAIL (rTRAIL) decreased the viability of C1498 cells. In contrast, EL4 cell viability was not affected by rTRAIL, indicating that EL4 cells were resistant to TRAIL-induced apoptosis, probably because of a functional defect in the intracellular signaling pathway downstream of DR5 (Supplementary Figure 4d). CD11b⁺Ly6G⁺ cells did not show an increase in the expression levels of FasL after polyI:C treatment (Supplementary Figure 3b). Taken together, ligands for the members of the TNF receptor family are not major factors for the inhibition of EL4 tumor growth by polyI:C treatment.

ROS/RNS induce caspase-8/3 activation and EL4 cell death. ROS/RNS, including PNT and H₂O₂, induce apoptosis of cancer cells.³⁸ When added exogenously, these

Figure 3 Sensitivity of EL4 cells to PNT or H₂O₂. (a, b, d and e) EL4 cells (1×10^4) were cultured in the presence of PNT (a and b) or H₂O₂ (d and e). After 24 h, cell viability was determined by a WST-1 assay (a and d), or after 8 h, caspase-8/3 activation was analyzed by immunoblotting (b and e). (c) EL4 cells (2×10^5) were pretreated with uric acid (2 mg/ml) for 1 h, and then cultured in the presence of PNT for 24 h. Cells were analyzed by flow cytometry. Dead cells were determined by 7-AAD staining. Data are shown as mean $\pm$ S.D. ($n=3$). Representative data of two independent experiments are shown

molecules lead to a specific cell-type activation of multiple caspases such as caspase-8, 9, and 3.^{39–41} As shown in Supplementary Figure 5, fluorescence levels of 2',7'-dichlorodihydrofluorescein diacetate (H2DCFDA), a cell-permeant indicator of ROS/RNS, were increased in CD11b⁺Gr1⁺ cells infiltrating into tumors in response to polyI:C treatment, suggesting that CD11b⁺Gr1⁺ cells respond to polyI:C to produce ROS/RNS. The *in vitro* treatment of EL4 cells with PNT resulted in an increase of apoptosis accompanied with caspase-8/3 activation (Figures 3a and b) that was abrogated by uric acid, a ROS/RNS scavenger (Figure 3c). H₂O₂ induces apoptosis in HeLa cells through the caspase-8/3 cascade.⁴² Similar to PNT, H₂O₂ treatment decreased the viability of EL4 cells and induced caspase-3 and caspase-8 activation (Figures 3d and e).

Next, we examined the gene expression profile for ROS/RNS production in polyI:C-treated CD11b⁺Gr1⁺ cells. PNT is formed by a reaction of nitric oxide (NO) with a superoxide anion (O₂⁻). NO and O₂⁻ are produced by iNOS and a NADPH oxidase 2 (NOX2, gp91^{phox})-containing molecular complex, respectively.³⁸ PolyI:C treatment increased protein and mRNA expression of iNOS in CD11b⁺Ly6G⁺ cells from the tumor and spleen (Figures 4a and b). The iNOS mRNA expression was increased by polyI:C *in vitro* (Supplementary Figure 6a). The polyI:C-induced expression of iNOS mRNA was significantly reduced in TICAM-1^{-/-} CD11b⁺Ly6G⁺ cells (Figure 4b and Supplementary Figure 6a). CD11b⁺Ly6G⁺ cells highly produce O₂⁻ in response to various types of stimuli through the activation of the NADPH oxidase complex localized in the plasma membrane. A similar result was observed for the expression of the NOX2 gene (Figure 4b).

To verify that CD11b⁺Ly6G⁺ cells produce PNT in response to polyI:C *in vivo*, we stained CD11b⁺Ly6G⁺ cells with aminophenyl fluorescein (APF) and hydroxyphenyl fluorescein (HPF), the cell-permeable fluorescent probes for the detection of ROS/RNS. APF detects hydroxyl radicals (•OH), peroxynitrite ions (PNT, ONOO⁻), and hypochlorite ions (OCI⁻). HPF detects PNT and OCI⁻, but rarely reacts with other ROS/RNS including O₂⁻, H₂O₂, and NO. The frequency of CD11b⁺Ly6G⁺ cells with increased fluorescence, representing an enhanced ROS/RNS production, was increased in tumor and spleen at 7 h after polyI:C treatment *in vivo* (Figure 4c and Supplementary Figure 6b). This response was specific to CD11b⁺Ly6G⁺ cells in both tumor and spleen because polyI:C treatment barely affected the fluorescence

intensity of Ly6G⁻ populations. To determine whether CD11b⁺Ly6G⁺ cells produce PNT in response to polyI:C treatment, an iNOS inhibitor, which blocks NO production by inhibiting iNOS activity, was added to tumor-bearing mice. The increase in the fluorescence intensity of APF-stained CD11b⁺Ly6G⁺ cells was largely attenuated in tumor-bearing mice treated with N^G-nitro-L-arginine methyl ester (L-NAME), an iNOS inhibitor (Figure 4d), suggesting that CD11b⁺Ly6G⁺ cells produced PNT in response to polyI:C stimulation. The APF fluorescence of TICAM-1^{-/-} CD11b⁺Ly6G⁺ cells was barely increased by treatment with polyI:C *in vivo* (Figure 4e and Supplementary Figure 6b), although iNOS mRNA remained slightly expressed (Figure 4b). Similar results were obtained when splenocytes of tumor-bearing mice were activated with polyI:C *in vitro* (Supplementary Figure 6c). TICAM-1-dependent PNT production in activated CD11b⁺Ly6G⁺ cells was confirmed by HPF staining (Figure 4f).

We then examined the response of CD11b⁺Ly6G⁺ cells to polyI:C treatment in IFNAR1^{-/-} mice. PolyI:C treatment did not induce ROS/RNS production in tumor-infiltrated CD11b⁺Ly6G⁺ cells from IFNAR1^{-/-} mice (Figure 4g). PolyI:C treatment induced mRNA expression of type-I IFNs by CD11b⁺Ly6G⁺ cells in tumor-bearing mice that was dependent on the TICAM-1 pathway (Supplementary Figure 3a). Recombinant type-I IFNs increased the production of ROS/RNS by CD11b⁺Ly6G⁺ cells (Supplementary Figure 7). Tumor-infiltrating CD11b⁺Ly6G⁺ cells also showed enhanced H₂O₂ production after polyI:C treatment (Figure 4h).

ROS/RNS are responsible for the antitumor activity of polyI:C-activated CD11b⁺Ly6G⁺ cells. Next, we determined whether ROS/RNS were involved in the tumor growth inhibition of EL4 cells by polyI:C-activated CD11b⁺Ly6G⁺ cells. We performed a co-implantation experiment (as in Figure 2d) to evaluate the possibility that ROS/RNS are effectors of polyI:C-activated CD11b⁺Ly6G⁺ cells. Mice were treated with uric acid or L-NAME after co-implantation of EL4 cells with CD11b⁺Ly6G⁺ cells. CD11b⁺Ly6G⁺ cell-induced inhibition of tumor growth was abrogated in mice treated with both reagents (Figures 5a and b). Furthermore, N6-(1-liminoethyl)-L-lysine dihydrochloride (L-NIL, an iNOS inhibitor) inhibited the cytotoxic activity of CD11b⁺Ly6G⁺ cells even after polyI:C activation (Figure 5c). Thus, ROS/RNS

Figure 4 ROS/RNS production by CD11b⁺Ly6G⁺ cells in tumor-bearing mice. (a–d) EL4 tumor-bearing mice were injected i.p. with PBS or polyI:C (200 μ g). (a) After 8 h, the tumor cell suspension was analyzed by flow cytometry using an anti-iNOS Ab. (b) After 3 h, CD11b⁺Ly6G⁺ cells were isolated from the spleen of tumor-bearing mice. iNOS and NOX2 mRNA expression in B6 WT or TICAM-1^{-/-} CD11b⁺Ly6G⁺ cells was determined by quantitative RT-PCR analysis ($n = 3$, $^*P < 0.05$). (c) The tumor cell suspension was stained with APF and anti-Ly6G Ab and analyzed by flow cytometry. (d) After 5 h, mice were injected i.p. with PBS or L-NAME (1.5 mg). The tumor cell suspension was analyzed by flow cytometry 2 h later. (e–g) EL4 tumor-bearing B6 WT (e, f, and g), TICAM-1^{-/-} (e and f), or IFNAR1^{-/-} (g) mice were injected with PBS or polyI:C (200 μ g). After 7 h, the tumor cell suspension was stained with APF or HPF and analyzed by flow cytometry. Graph represents the average of APF-stained Ly6G⁺ cells in the tumor cell suspension ($n = 3$, $^{**}P < 0.005$) (e). (h) EL4 tumor-bearing mice were injected with PBS or polyI:C. After 8 h, the tumor cell suspension was analyzed by flow cytometry using a BES-H₂O₂ reagent. All data are representative of at least two independent experiments

Figure 5 PolyI:C-activated CD11b⁺Ly6G⁺ cells inhibit tumor growth through ROS/RNS production. (a and b) CD11b⁺Ly6G⁺ cells were isolated from tumor-bearing mice after 4 h of treatment with PBS or polyI:C (200 μ g), and then mixed with EL4 cells. The mixture was injected s.c. into B6 WT mice, followed by an i.p. injection with 20 mg of uric acid (a) or 1.5 mg of L-NAME (b) (day 0). (c) EL4 tumor-bearing mice were injected i.p. with PBS or polyI:C (200 μ g). After 4 h, CD11b⁺Ly6G⁺ cells were isolated from spleens in the presence or absence of 50 μ M L-NIL. The cytotoxic activity of CD11b⁺Ly6G⁺ cells against EL4 cells was determined. Data are shown as mean $\pm$ S.D. ($n = 3$, $^{**}P < 0.005$). Representative data of two independent experiments are shown

Figure 6 Cancer cell lines are sensitive to ROS/RNS-induced cell death. (a) Tumor growth of B16 cells in an anti-Ly6G Ab-treated B6 WT mice. Abs were injected i.p. on days 12 and 16. PBS or polyI:C (100 μ g) was injected i.p. on days 13 and 17. (b) CD11b⁺Ly6G⁺ cells (1×10^6) isolated from PBS or polyI:C-treated B6 WT mice bearing B16 tumor were mixed with B16 cells (3×10^5), and the mixture was injected s.c. into B6 WT mice on day 0 ($n = 3-4$, $*P < 0.05$). (c) B16 tumor-bearing mice were injected i.p. with PBS or polyI:C (200 μ g). After 7 h, a single-cell suspension of tumor or spleen was stained with APF or HPF, and analyzed by flow cytometry. (d-f) EL4 cells (1×10^4), 3LL cells (1×10^4), B16 cells (0.25×10^4), and MC38 cells (1×10^4) were cultured for 24 h in the presence of PNT (d) or H₂O₂ (e). Cell viability was determined by the WST-1 assay. (f) Cleaved caspase-8 or cleaved caspase-3 was detected by immunoblotting after PNT treatment for 8 h. Data are representative of two independent experiments

production by polyI:C-activated CD11b⁺Ly6G⁺ cells is critical for their antitumor activity.

PNT and H₂O₂ induce caspase-8/3 activation and cell death in cancer cell lines. We investigated whether CD11b⁺Ly6G⁺ cells were generally important for tumor growth inhibition by polyI:C treatment using another tumor model. Inhibition of B16 tumor growth is largely dependent on NK cells in polyI:C therapy.⁵ The inhibitory effect of polyI:C on B16 tumor growth was partially abrogated in mice pretreated

with an anti-Ly6G Ab (Figure 6a). CD11b⁺Ly6G⁺ cells activated by polyI:C inhibited B16 tumor growth (Figure 6b). Furthermore, polyI:C induced ROS/RNS production from CD11b⁺Ly6G⁺ cells in tumor and spleen of mice implanted with B16, and also 3LL, and MC38 cells (Figure 6c and Supplementary Figure 8).

Next, to determine whether ROS/RNS induce caspase-8/3 activation and cytotoxicity in those cancer cell lines, we treated them with PNT and examined the cytotoxicity (Figure 6d). B16 cells were also treated with H₂O₂ (Figure 6e). PNT and H₂O₂

Figure 7 EL4 cells enhance PNT production by CD11b⁺Ly6G⁺ cells. (a) CD11b⁺Ly6G⁺ cells isolated from EL4 tumor-bearing mice were activated with PBS or polyI:C (100 μ g/ml) in the presence or absence of EL4 cells or recombinant GM-CSF (10 ng/ml). After 7 h, CD11b⁺Ly6G⁺ cells were stained with HPF and analyzed by flow cytometry. (b) CD11b⁺Ly6G⁺ cells were cultured with EL4 cells. Cells were separated by insertion of a transwell (0.4 μ m pore size) and activated with polyI:C as in (a). Graphs show the percentage of ROS/RNS-producing cells in total Ly6G⁺ cells. Data are representative of two independent experiments

exerted cytotoxicity against 3LL cells and B16 cells, as well as EL4 cells (Figures 6d and e); caspase-8/3 activation was also induced in these cell lines (Figure 6f). Although caspase activation was induced, MC38 cells were resistant to PNT-induced cell death. Among them, EL4 cells showed the highest sensitivity to both cytotoxicity and caspase-8/3 activation induced by PNT or H₂O₂ (Figures 3d and 6d). EL4 cells highly expressed caspase-8 mRNA as compared with the other cell lines (Supplementary Figure 9).

EL4 cells enhance PNT production by CD11b⁺Ly6G⁺ cells. After *in vitro* polyI:C stimulation, CD11b⁺Ly6G⁺ cells showed lower PNT production than those after *in vivo* stimulation (Figures 4f and 7a). Cancer cell-derived factors appear to modulate neutrophil function.⁴³ Thus, PNT levels in CD11b⁺Ly6G⁺ cells induced by polyI:C were measured in the presence of EL4 cells. Basal and polyI:C-induced PNT levels in CD11b⁺Ly6G⁺ cells were significantly increased by coexisting EL4 cells compared with CD11b⁺Ly6G⁺ cells alone (Figure 7a). EL4 cells secrete granulocyte macrophage colony-stimulating factor (GM-CSF), a survival factor of G-MDSCs or neutrophils.⁴⁴ However, in the presence of recombinant GM-CSF, polyI:C stimulation did not significantly increase PNT production by CD11b⁺Ly6G⁺ cells, although the basal levels of ROS/RNS production were increased (Figure 7a). EL4 cells failed to enhance PNT production by CD11b⁺Ly6G⁺ cells in a transwell, suggesting that cell-to-cell contact is required for this activity (Figure 7b). Thus, EL4 cells enhance ROS/RNS production by CD11b⁺Ly6G⁺ cells probably through stimulation of cell surface molecules that could increase the response of CD11b⁺Ly6G⁺ cells to polyI:C. This could explain why EL4 tumors are highly susceptible to CD11b⁺Ly6G⁺ cell-mediated antitumor activity of polyI:C, in addition to their high sensitivity to ROS/RNS-induced apoptosis.

Discussion

MHC class-I^{high} tumor cells are usually a target for TAA-specific CTLs. PolyI:C enhances cross-priming of CTLs by DCs, and PD-1/PD-L1 regulates tumor cytolysis by CTLs. In this study, we found that CD11b⁺Ly6G⁺ cells, but not CD8⁺ T cells, act as an effector for the polyI:C-induced tumor growth inhibition in the MHC class-I^{high} EL4 tumor implant model. The TICAM-1/IFNAR pathway is crucial to evoke the antitumor activity of CD11b⁺Ly6G⁺ cells through ROS/RNS production upon polyI:C treatment. This mechanism is different from the one mediated by TAMs that is also activated through the same signaling pathway, as observed in the 3LL tumor model. CD11b⁺Ly6G⁺ cells generally produced ROS/RNS in response to polyI:C treatment in mice implanted with various types of tumor cell lines. However, the response does not always lead to tumor regression because of the relatively strong tumoricidal activity of other antitumor effector cells induced by polyI:C that may cause invisible tumor shrinkage by CD11b⁺Ly6G⁺ cells. The TICAM-1/IFNAR pathway induces not only DC-primed CTLs, but also cytotoxicity of CD11b⁺Ly6G⁺ cells against MHC class-I^{high} EL4 lymphoma; this is also seen with MHC class-I-negative B16 melanoma. TICAM-1 in myeloid cells is a critical molecule for the antitumor immune activation encompassing DCs, TAMs, and tumor-associated CD11b⁺Ly6G⁺ cells.

Functional alterations of TAMs and MDSCs have shown to have both positive and negative impacts on tumor growth.^{45,46} TLRs could become targets for altering the phenotype of intratumor myeloid cells.^{47,48} MDSCs express an array of TLRs and their activation affects expansion and function of MDSCs. TLR2 or TLR4 activation in MDSCs may accelerate the development of immunosuppressive conditions.^{48,49} In contrast, activation of TLR9, TLR3, or MDA5 abolishes the suppressive activity of MDSCs and may contribute to tumor growth inhibition.^{26–28} In this study, we demonstrate that TICAM-1 is a critical adapter that determines the antitumor

activity of CD11b⁺Ly6G⁺ cells in RNA adjuvant therapy, and that both TICAM-1-inducible genes and TICAM-1-induced type-I IFNs are important for this antitumor mechanism. In combination with our previous data, we propose that myeloid cells expanded in cancer contribute to tumor growth inhibition, particularly under an RNA adjuvant treatment, rather than preventing the therapeutic effects through their immunosuppressive activity. This could be achieved by functional alteration of tumor-associated myeloid cells to exhibit tumor-killing activity. In this context, an RNA adjuvant can induce tumor regression even if immunosuppressive myeloid cells abundantly accumulate in tumors, such that the CTL response is insufficient to regress the tumor.

We found that the caspase-8/3 cascade is specifically activated in tumors after polyI:C treatment. Excessive amounts of extrinsic ROS/RNS induce caspase-8/3 activation in cancer cells, leading to apoptosis.^{40,41} We show that CD11b⁺Ly6G⁺ cells produce ROS/RNS including PNT and H₂O₂, in response to polyI:C stimulation. PNT and H₂O₂ efficiently induce the activation of the caspase-8/3 cascade and apoptosis of EL4 cells. Inducing cytotoxicity by ROS/RNS treatment in 3LL and B16 cells, but not MC38 cells, suggests that the susceptibility of tumors to the effector produced by CD11b⁺Ly6G⁺ cells depends on the cancer cell type. Among the cell lines tested, EL4 cells showed the highest sensitivity to PNT- or H₂O₂-induced apoptosis *in vitro*. The high sensitivity of EL4 cells to ROS/RNS may be explained by the fact that the mRNA levels of caspase-8 are relatively high in EL4 cells. Furthermore, EL4 cells supported polyI:C-induced activation of CD11b⁺Ly6G⁺ cells, suggesting that the tumor microenvironment is favorable for the activation of CD11b⁺Ly6G⁺ cells. Thus, CD11b⁺Ly6G⁺ cells play a critical role in the inhibition of EL4 tumor growth by polyI:C treatment. The antitumor activity of polyI:C-activated CD11b⁺Ly6G⁺ cells was abrogated by treatment of mice with uric acid or iNOS inhibitors. Because these reagents neutralize a broad range of ROS/RNS, other ROS/RNS may be synergistically involved in this cytotoxic effect.^{50–52}

We demonstrate that ROS/RNS production by CD11b⁺Ly6G⁺ cells requires the activation of TICAM-1/IFNAR signaling pathways. This response is partly mediated by TICAM-1-regulated induction of iNOS (NOS2) and NOX2 (Cybb) mRNA expression. ROS/RNS production is regulated by not only iNOS and NOX2 gene expression but also by protein–protein interactions in the TLR3/TICAM-1 signaling pathway.^{53–55} Furthermore, our data indicate that TICAM-1-dependent type-I IFN production is critical for ROS/RNS production as well as tumor growth inhibition by CD11b⁺Ly6G⁺ cells. The TICAM-1 and IFNAR pathways may cooperatively regulate the expression and activation of iNOS and NADPH oxidase complex. Further studies are required to identify the critical factor to control ROS/RNS production triggered by the TICAM-1/IFNAR pathway in CD11b⁺Ly6G⁺ cells.

Activation of TLR3/TICAM-1 pathway induces multifarious effector mechanisms for tumor regression in which NK cells, CTLs, and M1-shifted TAMs are involved.^{5,6,29} In this study, we further identified CD11b⁺Ly6G⁺ cells as a tumoricidal effector. As dsRNA treatment simultaneously induces activation of these effector cells, the sensitivity of cancer cells to the effector molecules ultimately determines each effector

cell-mediated tumor clearance. Tumors generally contain heterogeneous populations of cancer cells with variable phenotypes and likely become a target of different types of effector cells, effector molecules, or therapeutic reagents for immunotherapy.⁵⁶ Therefore, induction of CD11b⁺Ly6G⁺ cell-mediated cytotoxicity by dsRNA treatment in combination with other therapies using monoclonal Abs targeting cancer-associated molecules, immune checkpoint inhibitors, or CD8⁺ T cell-based therapy may be beneficial in some patients. We propose that the formation of a tumor-suppressive microenvironment is fundamentally induced by the TLR3/TICAM-1 pathway in myeloid cells, and this pathway is a promising target for the development of cancer immunotherapy.

Materials and Methods

Mice and tumor cells. Inbred C57BL/6 wild-type (B6 WT) mice were purchased from Clea Japan (Tokyo, Japan). TICAM-1^{−/−} and MAVS (IPS-1)^{−/−} mice were generated in our laboratory.^{5,57} IFNAR1^{−/−} mice were obtained from Dr. T Taniguchi (University of Tokyo, Tokyo, Japan). Mice (aged 6 to 10 weeks) were used in all experiments and maintained under specific pathogen-free conditions. The protocol was approved by the Committee on the Ethics of Animal Experiments in the Animal Safety Center, Hokkaido University, Japan. All mice were used according to the guidelines of the institutional animal care and use committee of Hokkaido University, who approved this study as ID number 08-0290 and 13-0043. EL4 cells were obtained from Dr. Sato (Sapporo Medical University, Sapporo, Japan). The B16D8 cell line was established in our laboratory as a subline of B16 melanoma.⁵⁸ 3LL, MC38, and C1498 cell lines were purchased from ATCC (American Type Culture Collection, Manassas, VA, USA). EL4, B16D8, 3LL, and C1498 cells were cultured at 37 °C under 5% CO₂ in RPMI-1640 medium supplemented with 10% fetal bovine serum (FBS), 100 U/ml penicillin, and 100 µg/ml streptomycin. MC38 cells were cultured in RPMI-1640 medium supplemented with 10% FBS, 50 µM 2-ME, 2 mM L-glutamine, 1 mM sodium pyruvate, 100 U/ml penicillin, and 100 µg/ml streptomycin (Life Technologies, Carlsbad, CA, USA).

Tumor challenge and polyI:C treatment. Mice were shaved at the back and injected s.c. with EL4 cells (1 × 10⁶), B16D8 cells (6 × 10⁵), 3LL cells (1 × 10⁶), or MC38 cells (1 × 10⁶) resuspended in 200 µL of PBS(−). Tumor size was measured using a caliper. Tumor volume was calculated using the following formula: tumor volume (cm³) = (long diameter) × (short diameter)² × 0.4. PolyI:C (GE Healthcare, San Francisco, CA, USA) with no detectable LPS was injected s.c. (100 µg/head) or intraperitoneally (i.p.; 200 µg/head). When the tumors reached an average volume of 0.4–0.6 cm³, the treatment was started and repeated every 4 days. In some experiments, Ly6G⁺ cells (1 × 10⁶) isolated from the spleen of tumor-bearing mice (4 h of pretreatment with polyI:C) were mixed with EL4 cells (0.5 × 10⁶) in 200 µL of PBS(−), and then implanted s.c. into tumor-free B6 WT mice. Uric acid (20 mg/head; Sigma-Aldrich, St. Louis, MO, USA) or L-NAME (1.5 mg/head; Sigma-Aldrich) were injected i.p. into tumor-bearing mice after implantation of the cell mixture.

Immunohistochemistry. Tumors were fixed with 10% neutralized buffered formalin at 4 °C for 4 h, equilibrated with 15% sucrose in PBS(−) for 1 h, and then with 30% sucrose in PBS(−) for 16–18 h. Tissue samples were embedded in Tissue Tek O.C.T compound (Sakura Finetek Japan, Tokyo, Japan), frozen, and stored at −80 °C until use. The tissue block was cut at a thickness of 10 µm. For the TUNEL assay, tumor sections were stained using the *In Situ* Cell Death Detection Kit, Fluorescein (Roche, Basel, Switzerland). For detection of caspase-3 activation, Abs against cleaved caspase-3 (Asp175) (5A1E) and an Alexa488-anti-rabbit IgG secondary Ab (Life Technologies) were used.

Cell isolation and culture. CD11b⁺Ly6G⁺ cells were isolated from a single-cell suspension from the spleen of polyI:C- or PBS-injected mice by using a biotin-conjugated anti-Ly6G monoclonal Ab (1A8) (Biolegend, San Diego, CA, USA) and Streptavidin Microbeads (Miltenyi Biotec, Bergisch Gladbach, Germany) according to the manufacturer's instructions. In these purification steps, two rounds of positive selection were performed to increase purity. We routinely prepared Ly6G⁺

cells at >95% purity and almost 100% of Ly6G⁺ cells expressed CD11b (Supplementary Figure 2). Isolated CD11b⁺Ly6G⁺ cells were cultured in Opti-MEM (Life Technologies) supplemented with or without 0.5% FBS for *in vitro* polyI:C stimulation or cytotoxicity assays, respectively. To inhibit iNOS activity, EL4 tumor-bearing mice were injected i.p. with L-NAME (1.5 mg/head) or L-NIL (0.5 mg/head) 5 h after polyI:C treatment. After 2 h, CD11b⁺Ly6G⁺ cells were isolated from the spleen and used for the cytotoxicity assay.

Flow cytometry. Single-cell suspensions isolated from tumors or spleens were stained with fluorescent dye-labeled Abs after blockade with an anti-CD16/32 Ab (93). The following Abs were used: FITC-anti-CD11b (M1/70), PE-anti-GR1 (RB6-8C5), APC- or FITC-anti-Ly6G (1A8), FITC-anti-CD11c (N418), PE- or APC-anti-F4/80 (BM8), PE-anti-NK1.1 (PK136), PE-anti-CD49b (DX5), PE-anti-CD3e (145-2C11), FITC-anti-CD4 (GK1.5), FITC-anti-CD8a (53-6.7), and PE-anti-CD19 (MB19-1) (eBioscience, San Diego, CA, USA or Biolegend). For detection of intracellular ROS/RNS, fluorescent probes were applied. Cells were stained with 5 μ M APF, 5 μ M HPF (SEKISUI Medical, Tokyo, Japan), and 5 μ M BES-H₂O₂-Ac (Wako, Osaka, Japan) at 25 °C for 15 min, followed by staining with an APC-anti-Ly6G Ab (1A8) at 25 °C for 15 min. Samples were analyzed by a FACS Calibur or FACS Aria II (BD Biosciences, San Jose, CA, USA); data analysis was performed using Flow Jo (Tree Star, Ashland, OR, USA).

In vivo depletion. The *in vivo* depletion of cells was achieved by i.p. injection of ascites containing monoclonal Abs against CD8 β (53-6.7), CD4 (GK1.5), NK1.1 (PK136), or Gr1 (RB6-8C5). For Ly6G⁺ cell depletion, 150 μ g of Ultra-LEAF purified anti-mouse Ly6G Ab (1A8) (Biolegend) was injected i.p. into mice. Ultra-LEAF purified rat IgG2a (Biolegend) was used as an isotype matched control Ab. Antibodies were injected 1 day before the polyI:C treatment. Depletion of cells in tumor-bearing mice was confirmed by flow cytometry of spleen and tumor cell suspensions.

Immunoblotting. Tumors excised from mice or cancer cell lines were lysed in 1% NP-40, 10 mM Tris-HCl (pH 7.2) supplemented with a complete protease inhibitor cocktail (Roche) and incubated for 30 min on ice. The lysate was centrifuged at 15 000 r.p.m. for 10 min to remove cell debris. The supernatant was mixed with a 2 $\times$ SDS-PAGE sample buffer and heated at 85 °C for 5 min. Samples were stored at -30 °C until use. An equal amount (50 μ g) of protein was analyzed by SDS-PAGE (12% acrylamide). Abs against cleaved caspase-3 (Asp175) (5A1E), cleaved caspase-8 (Asp387), full-length caspase-9, full-length caspase-12 (Cell Signaling Technology, Danvers, MA, USA), and HRP-conjugated goat anti-rabbit IgG Ab (Life Technologies) were used for detection of caspases.

Cytotoxic activity assay. Cytotoxic activity of CD11b⁺Ly6G⁺ cells was measured by the following procedure. EL4 cells (1 $\times$ 10⁶) were incubated in 1 ml of 0.5 μ M carboxyfluorescein diacetate succinimidyl ester (CFSE) in PBS at 37 °C for 15 min. After washing 2 times with RPMI-1640 supplemented with 10% FBS, CFSE-labeled EL4 cells were cultured in Opti-MEM (Life Technologies) containing 10 ng/ml recombinant mouse GM-CSF (Peprotech, Rocky Hill, NJ, USA) for 4 h. CD11b⁺Ly6G⁺ cells were isolated from the spleen of tumor-bearing mice, suspended in Opti-MEM, and mixed with CFSE-labeled EL4 cells. After 20–24 h of incubation, dead cells were detected with the SYTOX AADvanced Dead Cell Stain (Life Technologies) according to the manufacturer's instructions. The proportion of dead cells in CFSE⁺ (EL4 cells) was measured by FACS Calibur or FACS Aria II. Cytotoxicity percentage was calculated with the following formula: ((Live cell %/Dead cell% effector) – (Live cell%/Dead cell% control)) $\times$ 100. WST-1 assay was performed according to the manufacturer's instructions (Dojindo, Kumamoto, Japan).

RNA isolation and RT-PCR analysis. Total RNA from CD11b⁺Ly6G⁺ cells was isolated with the TRIzol reagent (Life Technologies) or the RNeasy mini kit (QIAGEN, Venlo, Netherlands) according to the manufacturer's instructions. Complementary DNA (cDNA) was synthesized using a High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA, USA). Real-time PCR was performed with Power SYBR Green PCR Master Mix (Applied Biosystems) and a StepOne Real-time PCR System (Applied Biosystems). Expression of the cytokine genes was normalized to the expression of mouse glyceraldehyde 3-phosphate dehydrogenase (GAPDH). We used following primer pairs: mouse GAPDH forward, 5'-GCCTGGAGAAACCTGCCA-3', GAPDH reverse, 5'-CCCTCAGATGCCTGCTTCA-3'; mouse iNOS (NOS2) forward, 5'-

CAGCTGGGCTGTACAAACCTTC-3', mouse iNOS (NOS2) reverse, 5'-CATT GGAAGTGAAGCGTTTCG-3'; mouse NOX2 (pg91phox, Cybb) forward, 5'-TGC AGTGCTATCATCCAAGC-3', mouse NOX2 (pg91phox, Cybb) reverse, 5'-CTTT CTCAGGGTTCCAGTG-3'. Data were analyzed by the $\Delta\Delta$ Ct method.

Statistical analysis. Statistically significant differences between two groups were determined using Student's *t*-test.
