CLINICAL UTILITY GENE CARD

Clinical utility gene card for: blue cone monochromatism

Susanne Kohl^{*1} and Christian P Hamel²

European Journal of Human Genetics (2011) **19**, doi:10.1038/ejhg.2010.232; published online 26 January 2011

1. DISEASE CHARACTERISTICS

1.1 Name of the disease (synonyms)

Blue cone monochromatism (BCM); colour blindness, blue-mono-cone-monochromatic type (CBBM).

1.2 OMIM# of the disease

303700.

1.3 Name of the analysed genes or DNA/chromosome segments

OPN1LW/OPN1MW gene cluster on the X-chromosome, Chr. Xq28.

1.4 OMIM# of the gene(s)

OPN1LW, *RCP*, *CBP*; 303900, *OPN1MW*, *GCP*, *CBD*; 303800.

1.5 Mutational spectrum

Large deletions spanning the locus control region and/or the promoters and/or the genes; genomic rearrangements – unequal crossing-over, resulting in single red and/or red/green hybrid genes; inactivating missense mutations (most common missense mutation c.607T>C p.C203R).^{1,2}

1.6 Analytical methods

Duplex PCRs, PCR/RFLP defining the structure and integrity of the *OPN1LW/OPN1MW* gene cluster, DNA sequencing for point mutations.

1.7 Analytical validation

Confirmation of mutation in an independent biological sample of the index case and/or in an affected subject.

In case of a genomic deletion, confirmation by duplex PCR and/or second technique; if possible define breakpoints by long-distance PCR.

1.8 Estimated frequency of the disease

(incidence at birth ('birth prevalence') or population prevalence): 1:100 000.

1.9 If applicable, prevalence in the ethnic group of investigated person

Unknown.

1.10 Diagnostic setting

	Yes	No
A. (Differential) diagnostics	☒	☐
B. Predictive testing	☐	☒
C. Risk assessment in relatives	☒	☐
D. Prenatal	☒	☐

Comment:

As penetrance is 100% and since disease is present from birth, the test is not used for predictive testing.

2. TEST CHARACTERISTICS

Genotype or disease		A: True positives	C: False negatives
		B: False positives	D: True negatives
	Present	Absent	
Test			
Positive	A	B	Sensitivity: A/(A+C)
			Specificity: D/(D+B)
Negative	C	D	Positive predictive value: A/(A+B)
			Negative predictive value: D/(C+D)

2.1 Analytical sensitivity

(proportion of positive tests if the genotype is present)

Over 90%.

2.2 Analytical specificity

(proportion of negative tests if the genotype is not present)

Above 95%.

2.3 Clinical sensitivity

(proportion of positive tests if the disease is present)

The clinical sensitivity can be dependent on variable factors such as age or family history. In such cases, a general statement should be given, even if a quantification can only be made case by case.

Above 90%.

2.4 Clinical specificity

(proportion of negative tests if the disease is not present)

The clinical specificity can be dependent on variable factors such as age or family history. In such cases, a general statement should be given, even if a quantification can only be made case by case.

Above 95%.

2.5 Positive clinical predictive value

(life-time risk to develop the disease if the test is positive)

Nearly 100% penetrance with little variability in disease expression (macular degeneration and rarely progression is observed^{3,4}).

2.6 Negative clinical predictive value

(probability not to develop the disease if the test is negative)

Assume an increased risk based on family history for a non-affected person. Allelic and locus heterogeneity may need to be considered.

Index case in that family had been tested:

Nearly 100% if genotype identified in index case. Mutations and rearrangements in the *OPN1LW/OPN1MW* gene cluster and locus control region are the only cause of BCM.

Carriership testing in female family members is limited.

Index case in that family had not been tested:

This approach cannot be supported.

3. CLINICAL UTILITY

3.1 (Differential) diagnosis: the tested person is clinically affected

(To be answered if in 1.10 'A' was marked)

3.1.1 Can a diagnosis be made other than through a genetic test?

No	☐ (continue with 3.1.4)
Yes	☒
	Clinically. ☒
	Imaging. ☐
	Endoscopy. ☐
	Biochemistry. ☐
	Electrophysiology. ☒
	Other (please describe): ☒
	Comment:
	Standard clinical ophthalmological evaluation and testing
	Electrophysiological examination (electroretinography)
	Psychophysical testings (colour vision, dark adaptometry)

3.1.2 Describe the burden of alternative diagnostic methods to the patient

Initial clinical and electrophysiological investigations are always necessary before molecular genetic analysis is prescribed. However, clinical investigations are sometimes incomplete in young children (approximate visual acuity, ERG recorded with skin electrodes and/or hand-held, non-Ganzfeld stimulator). Complete clinical investigations and ERG recording may require general anaesthesia.

3.1.3 How is the cost effectiveness of alternative diagnostic methods to be judged?

Clinical and electrophysiological testing in young children may require anaesthesia and hospitalisation.

3.1.4 Will disease management be influenced by the result of a genetic test?

No	☐
Yes	☒
Therapy (please describe)	There is no specific therapy available.
Prognosis (please describe)	The genetic diagnosis essentially contributes to the classification of cases with similar clinical features. This is the basis for prognostic statements. Blue cone monochromatism is expected to be a stationary disease, yet in rare cases macular degeneration can occur. ^{3,4}
Management (please describe)	Genetic testing has considerable consequence on clinical management as the condition is usually stationary. Consequently, learning Braille and education in specialized schools are not required as opposed to cases with either Leber congenital amaurosis or certain cases of cone dystrophy. Both these latter conditions are differential diagnoses of blue cone monochromatism, in which patients become progressively blind. Patients should be informed about the possibilities of filtering glasses or contact lenses (red tinted or brown) to reduce photophobia and improve contrast sensitivity. Low-vision aids include high-powered magnifiers for reading.

3.2 Predictive setting: the tested person is clinically unaffected but carries an increased risk based on family history

(To be answered if in 1.10 'B' was marked)

3.2.1 Will the result of a genetic test influence lifestyle and prevention?

If the test result is positive (please describe):

Genetic analysis can guide prospective parents concerned about the risk of having affected children and will help in management of the disease in affected patients (see 3.1.4).

If the test result is negative (please describe):

This will lead to reconsider the clinical diagnosis. The diagnosis of blue cone monochromatism will therefore be either confirmed, or excluded and redirected to achromatopsia, for example.

3.2.2 Which options in view of lifestyle and prevention does a person at-risk have if no genetic test has been done (please describe)?

Regular ophthalmological follow-up examination.

3.3 Genetic risk assessment in family members of a diseased person

(To be answered if in 1.10 'C' was marked)

3.3.1 Does the result of a genetic test resolve the genetic situation in that family?

Yes, X-linked inheritance.

3.3.2 Can a genetic test in the index patient save genetic or other tests in family members?

No.

3.3.3 Does a positive genetic test result in the index patient enable a predictive test in a family member?

Yes, for recurrence risk and female carriers.

3.4 Prenatal diagnosis

(To be answered if in 1.10 'D' was marked)

3.4.1 Does a positive genetic test result in the index patient enable a prenatal diagnostic?

Genetic counselling is mandatory. Prenatal diagnosis is increasingly asked by at-risk couples and use of prenatal diagnostic test varies with national/ethical customs.

4. IF APPLICABLE, FURTHER CONSEQUENCES OF TESTING

Please assume that the result of a genetic test has no immediate medical consequences. Is there any evidence that a genetic test is nevertheless useful for the patient or his/her relatives? (Please describe)

Correct diagnosis has implications on education and professional career choices (low vision).

Parents are given accurate information on the cause of the disease, progression and recurrence risk.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

ACKNOWLEDGEMENTS
