CLINICAL UTILITY GENE CARD

Clinical utility gene card for: Cystinuria

Thomas Eggermann^{*,1}, Klaus Zerres¹, Virginia Nunes^{2,3,4}, Mariona Font-Llitjós^{2,3,4}, Luigi Bisceglia⁵, Anthoula Chatzikyriakidou⁶, Luca dello Strologo⁷, Elon Pras⁸, John Creemers⁹ and Manuel Palacin¹⁰

European Journal of Human Genetics (2012) 20, doi:10.1038/ejhg.2011.163; published online 24 August 2011

1. DISEASE CHARACTERISTICS

1.1 Name of the disease (synonyms)

Cystinuria; currently two additional autosomal recessive contiguous cystinuria-associated syndromes in 2p21 are known: HCS and the 2p21 deletion syndrome.

1.2 OMIM# of the disease

Cystinuria: 220100, HCS: 606407.

1.3 Name of the analysed genes or DNA/chromosome segments

SLC3A1, *SLC7A9*, 2p21.

1.4 OMIM# of the gene(s)

SLC3A1: 104614,

SLC7A9: 604144.

1.5 Mutational spectrum

Point mutations, multiexon deletions and duplications, genomic rearrangements.^{1–8}

1.6 Analytical methods

Sanger sequencing of the total coding region and the exon–intron boundaries of the *SLC3A1* and *SLC7A9* genes. MLPA, qPCR and microarray typing for detection of multiexon and whole gene imbalances.

1.7 Analytical validation

All mutations identified have to be confirmed by a second, independent test (PCR, qPCR, sequencing, MLPA). The segregation of the mutation should be confirmed in the parents and further relatives. Pathogenicity of novel missense alterations has to be verified by testing a set of at least 100 control chromosomes of the same ethnic origin and by *in-silico* prediction methods. To confirm their pathogenic nature, splice site variants should be characterised by cDNA analysis.

1.8 Estimated frequency of the disease

(incidence at birth ('birth prevalence') or population prevalence)

Cystinuria: birth prevalence: 1:7000

(HCS/2p21 deletions: 1:1 000 000)

1.9 If applicable, prevalence in the ethnic group of investigated person

Cystinuria: 1:2500 in Jewish Israelis of Libyan origin, 1:100 000 in Sweden.

HCS: allele frequencies for the most common deletions in Belgium: 1:333–1:7700.⁹

1.10 Diagnostic setting

	Yes	No
A. (Differential) diagnostics	☒	☐
B. Predictive testing	☒	☐
C. Risk assessment in relatives	☒	☐
D. Prenatal	☒	☐

Comment:

Large genomic deletions in 2p21 include at least the *SLC3A1* and *PREPL* genes; in the homozygote state the 2p21 deletion is associated with the hypotonia-cystinuria syndrome.

2. TEST CHARACTERISTICS

Genotype or disease		A: True positives	C: False negatives
		B: False positives	D: True negatives
		Present	Absent
Test			
Positive	A	B	Sensitivity: A/(A+C) Specificity: D/(D+B)
Negative	C	D	Positive predictive value: A/(A+B) Negative predictive value: D/(C+D)

2.1 Analytical sensitivity

(proportion of positive tests if the genotype is present)

Depending on the ethnic origin and the applied methods:
 50–100%.

¹Institut für Humangenetik, RWTH Aachen, Aachen, Germany; ²Molecular Genetics laboratory-IDIBELL, Barcelona, Spain; ³Genetics Section, Physiological Sciences II Department, University of Barcelona-IDIBELL, Barcelona, Spain; ⁴U730 CIBERER, Barcelona, Spain; ⁵UOC Genetica Medica, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; ⁶Genetics Unit, University Hospital, Ioannina, Greece; ⁷Urology and Nephrology Department, Bambino Gesù Children's Hospital, Institute for Scientific Research (IRCCS), Rome, Italy; ⁸The Danek Gertner Institute of Human Genetics, Sheba Medical Center, Tel Hashomer, Israel; ⁹Center for Human Genetics, K.U. Leuven, Belgium; ¹⁰Institute of Research in Biomedicine, U731 CIBERER, University of Barcelona, Barcelona, Spain

*Correspondence: Professor Dr T Eggermann, Institute of Human Genetics, University Hospital Aachen, Pauwelsstr. 30, 52074 Aachen, Germany. Tel: +49 241 808 8008; Fax: +49 241 808 2394; E-mail: teggermann@ukaachen.de

2.2 Analytical specificity

(proportion of negative tests if the genotype is not present)

> 98%.

2.3 Clinical sensitivity

(proportion of positive tests if the disease is present)

The clinical sensitivity can be dependent on variable factors such as age or family history. In such cases a general statement should be given, even if a quantification can only be made case by case.

Depending on the ethnic origin and the applied methods:

50–100% (if the urinary excretion patterns revealed an increased cystine excretion).

2.4 Clinical specificity

(proportion of negative tests if the disease is not present)

The clinical specificity can be dependent on variable factors such as age or family history. In such cases a general statement should be given, even if a quantification can only be made case by case.

> 98%.

2.5 Positive clinical predictive value

(life-time risk of developing the disease if the test is positive)

SLC3A1: increased urinary cystine excretion: 100%, kidney stone formation: 94%.

SLC7A9: increased urinary cystine excretion: 100%, kidney stone formation: 94%.

(in homozygotes or compound/mixed heterozygotes)

For *SLC7A9* heterozygotes an increased urinary cystine excretion can be observed in 86–90% of cases and kidney stone formation in 2–18% of cases.

Polymorphisms of the *SLC7A9* gene probably affect the clinical course in *SLC7A9* mutation carriers.³

2.6 Negative clinical predictive value

(probability not to develop the disease if the test is negative)

Assume an increased risk based on family history for a non-affected person. Allelic and locus heterogeneity may need to be considered.

Index case in that family had been tested:

> 99%.

Index case in that family had not been tested:

Depending on the affected gene and the degree of relationship.

3. CLINICAL UTILITY

3.1 (Differential) diagnosis: the tested person is clinically affected

(To be answered if in 1.10 'A' was marked)

3.1.1 Can a diagnosis be made other than through a genetic test?

No	☐ (continue with 3.1.4)	
Yes	☒	
	Clinically	☐
	Imaging	☐
	Endoscopy	☐
	Biochemistry	☒
	Electrophysiology	☐
	Other (please describe)	

3.1.2 Describe the burden of alternative diagnostic methods to the patient?

In the majority of cases the initial diagnosis of cystinuria is achieved first by the identification of a cystine stone and then confirmed by

biochemical or genetic data. Exception is the possible request of a diagnosis by siblings of affected subjects, who had not yet formed renal stones. In some situations, an increase in urinary cystine and dibasic amino acids excretion (on qualitative testing) does not allow a definite prognosis, because of the difficulty to differentiate between homozygotes (or compound heterozygotes) or heterozygotes. In these cases genetic testing might help to clarify the diagnosis. Alternatively, relatively low arginine and ornithine levels in heterozygotes in quantitative analysis of urine amino acids can also differentiate between the two.

3.1.3 How is the cost effectiveness of alternative diagnostic methods to be judged?

The cost effectiveness of biochemical and chemical urinary and stone analyses is very high.

3.1.4 Will disease management be influenced by the result of a genetic test?

No		
Yes	☒	
	Therapy (please describe)	Prevention of stone formation by methods to (a) decrease cystine excretion, (b) to decrease urinary cystine concentration and (c) to reduce cystine to the more soluble cysteine (see Bisceglia <i>et al</i>). ¹
	Prognosis (please describe)	Recurrent lithiasis (age at first stone formation: for 14–28% of patients <3 years and 35–40% of patients between 11 and 20 years). Life expectancy might be reduced.
	Management (please describe)	(1) A high fluid intake of around 4–5l a day is recommended. (2) Alkalinization of urine with citrate or bicarbonate. (3) Chelation therapy with D-penicillamine or tiopronin (α -mercaptopyronylglycine), and reduce the free urinary cystine concentration to <1000 μ mol/l (ideally <500 μ mol/l). D-penicillamine is more easily available, but can have serious adverse effects (agranulocytosis and proteinuria), therefore requiring close monitoring and careful dose titration. (4) Occasionally, surgical intervention is needed.

Patients with a preclinical diagnosis and therefore not yet formed renal stones, should not be treated with cystine-binding drugs (tiopronin or penicillamine). They should, however, be encouraged to drink water, particularly before going to sleep, to dilute urine overnight. The use of potassium citrate should also be discussed, at least in those patients with highest level of cystine.

3.2 Predictive setting: the tested person is clinically unaffected but carries an increased risk based on family history

(To be answered if in 1.10 'B' was marked)

3.2.1 Will the result of a genetic test influence lifestyle and prevention?

If the test result is positive (please describe):

Prevention of stone formation (see Bisceglia *et al*)¹ by dietary methods.

If the test result is negative (please describe):

No.

3.2.2 Which options in view of lifestyle and prevention do a person at-risk have if no genetic test has been done (please describe)?

Reducing the intake of protein is really difficult: reducing cystine intake is ineffective as it is converted from methionine and compliance

to a lifelong reduction to protein is unlikely to be followed by the patient. Increase in oral fluid assumption is instead easy to achieve and it must be recommended, in particular in case of diarrhoea, vomit, fever or other reasons for temporary dehydration.

3.3 Genetic risk assessment in family members of a diseased person (To be answered if in 1.10 'C' was marked)

3.3.1 Does the result of a genetic test resolve the genetic situation in that family?

Yes.

3.3.2 Can a genetic test in the index patient save genetic or other tests in family members?

Yes: in case of a known familial mutation, carriership can be confirmed or excluded.

3.3.3 Does a positive genetic test result in the index patient enable a predictive test in a family member?

It is often asked for by parents of an affected child who have further children. It should be offered if informative biochemical data are not available to prove the diagnosis as type B carriers (heterozygote carriers with only one SLC7A9 mutation) often have a confounding urinary pattern. Positive result may induce positive behaviour in order to reduce future stone formation.

3.4 Prenatal diagnosis

(To be answered if in 1.10 'D' was marked)

3.4.1 Does a positive genetic test result in the index patient enable a prenatal diagnosis?

Yes, but a prediction of the clinical course is not possible.^{6,10}

4. IF APPLICABLE, FURTHER CONSEQUENCES OF TESTING

Please assume that the result of a genetic test has no immediate medical consequences. Is there any evidence that a genetic test

is nevertheless useful for the patient or his/her relatives? (Please describe)

Yes, for the family genetic counselling is always useful.

CONFLICT OF INTEREST

The authors declare no conflict of interests.
