CLINICAL UTILITY GENE CARD

Clinical utility gene card for: Loeys-Dietz syndrome (*TGFBR1/2*) and related phenotypes

Mine Arslan-Kirchner^{*,1}, Jörg T Epplen², Laurence Faivre³, Guillaume Jondeau⁴, Jörg Schmidtke¹, Anne De Paepe⁵ and Bart Loeys⁵

European Journal of Human Genetics (2011) 19, doi:10.1038/ejhg.2011.68; published online 27 April 2011

1. DISEASE CHARACTERISTICS

1.1 Name of the disease (synonyms)

Loeys-Dietz syndrome (LDS), Marfan syndrome type 2, Marfan-related phenotype.

1.2 OMIM# of the disease

609192.

1.3 Name of the analyzed genes or DNA/chromosome segments

TGFBR1/TGFBR2.

1.4 OMIM# of the gene(s)

190181 and 190182.

1.5 Mutational spectrum

As the initial description of the disease, several hundreds of mutations have been found, of which circa 75% are located in *TGFBR2* and circa 25% in *TGFBR1*. Both missense, splice site and nonsense mutations have been reported. Most missense mutations occur in the intracellular serine threonine kinase domain of both TGF beta receptors.

1.6 Analytical methods

Direct sequencing of all exons with intron/exon boundaries of both genes. So far no deletions/duplications have been reported after screening by MLPA, so the usefulness of MLPA for testing of the *TGFBR1/2* need to be determined (personal communication).

1.7 Analytical validation

Sequencing of both strands. When a mutation is identified, confirmation in a second independent DNA sample is recommended.

1.8 Estimated frequency of the disease (incidence at birth ('birth prevalence') or population prevalence)

No data about prevalence have been reported. However, the frequency of mutation in the *TGFBR2* gene seems to be more frequent than mutation in the *TGFBR1* gene, and both seem to be less frequent than *FBN1* mutation.

1.9 If applicable, prevalence in the ethnic group of investigated person

Not applicable.

1.10 Diagnostic setting

	Yes	No
A. (Differential) diagnostics	☒	☐
B. Predictive testing	☒	☐
C. Risk assessment in relatives	☒	☐
D. Prenatal	☒	☐

Comment:

TGFBR1/2 testing is indicated as the first test to perform in the following indications:

- (1) Patients with characteristic triad of LDS: hypertelorism, cleft palate/bifid uvula and aortic/arterial aneurysms/tortuosity.¹
- (2) Patients with aortic/arterial aneurysm (specifically early onset of aortic aneurysm and history of early death) with variable combination of other features including arachnodactyly, camptodactyly, club feet, craniosynostosis (all types), mental retardation, blue sclerae, thin skin with atrophic scars, easy bruising, joint hypermobility, bicuspid aortic valve (BAV) and patent ductus arteriosus (PDA), atrial and ventricular septum defects (ASD/VSD).¹
- (3) Patients with a vascular Ehlers-Danlos like phenotype with normal collagen type III biochemistry, but typical skin findings (thin skin, atrophic scars, easy bruising) and joint hypermobility.²
- (4) Patients with Marfan-like phenotype, especially those without ectopia lentis but with aortic/arterial aneurysms, craniofacial features (malar hypoplasia and retrognathia) and skeletal features not fulfilling Ghent criteria for MFS (arachnodactyly, pectus deformities, scoliosis, joint laxity and dolichostenomelia).^{2,3}
- (5) Families with autosomal dominant thoracic aortic aneurysms, especially those families with precocious aortic/arterial dissection, aortic disease beyond the aortic root (including cerebral arteries), aortic/arterial tortuosity, association with ASD/VSD/PDA. Mild marfanoid skeletal features may be present.^{4,5}

TGFBR1/2 testing is also indicated as a secondary test in patients in whom *FBN1* testing remains negative despite MFS-like phenotype.

TGFBR1/2 mutations have been described in Shprintzen-Goldberg, but most of these patients have many characteristics in common with

¹Institute of Human Genetics, Hannover Medical School, Hannover, Germany; ²Human Genetics Bochum, Ruhr University Bochum, Bochum, Germany; ³Centre de Génétique, Centre Hospitalier Universitaire de Dijon, Dijon, France; ⁴Service de Cardiologie, CHU Hôpital Xavier Bichat – Claude Bernard, Paris, France; ⁵Center for Medical Genetics, Ghent University, Ghent, Belgium

LDS. Many patients with true Shprintzen-Goldberg syndrome do not have *TGFBR1/2* mutations.^{1,6}

Although initially two clinical presentations were distinguished (LDS type I with more typical craniofacial findings and LDS type II with more prominent cutaneous findings), it is now recognized that LDS is a continuum that includes a wide range of clinical presentations. The respective clinical spectrum of *TGFBR1* and *TGFBR2* mutation is not fully recognized.

2. TEST CHARACTERISTICS

Genotype or disease		A: True positives	C: False negative
		B: False positives	D: True negative
Present		Absent	
Test			
Positive	A	B	Sensitivity: A/(A+C) Specificity: D/(D+B)
Negative	C	D	Positive predictive value: A/(A+B) Negative predictive value: D/(C+D)

2.1 Analytical sensitivity (proportion of positive tests if the genotype is present)

Nearly 100%.

The possibility of preferential amplification of one allele, if primers are localized on a SNP (hampering primer binding) or because of deletion (making amplification impossible) exists, although these events are exceptional.

Classical criteria for determining the pathogenicity of a mutation are the following:

- Nonsense mutation
- Splice site mutation affecting canonical splice sequence or shown to alter splicing on mRNA/cDNA level
- Out of frame and inframe deletion/insertion
- *De novo* missense mutation (with proven paternity and absence of disease in parents)
- Missense mutation previously been shown to segregate in Loews-Dietz family
- For other missense mutations, the segregation in family should be checked, if possible, as well as the absence of the variant in 400 ethnically matched control chromosomes.

2.2 Analytical specificity (proportion of negative tests if the genotype is not present)

Nearly 100%.

2.3 Clinical sensitivity (proportion of positive tests if the disease is present)

The clinical sensitivity can be dependent on variable factors such as age or family history. In such cases a general statement should be given, even if a quantification can only be made case by case.

Unknown, dependent on the depth of clinical evaluation and cardiovascular imaging.

2.4 Clinical specificity (proportion of negative tests if the disease is not present)

The clinical specificity can be dependent on variable factors such as age or family history. In such cases a general statement should be given, even if a quantification can only be made case by case.

By definition 100%.

Mutations within the *TGFBR1* and *TGFBR2* genes have been reported in patients with LDS.^{1,2}

TGFBR1/2 mutations have also been found in MFS or suspected MFS.³ Sakai *et al*⁷ found one patient with a *TGFBR1* mutation (2%) and two *TGFBR2* mutations (4%) out of a series of 49 MFS-like patients; Mätyäs *et al*⁸ reported 10 *TGFBR1* or *TGFBR2* mutations in 70 unrelated individuals with MFS-like phenotypes who previously tested negative for mutations in *FBN1*; Singh *et al*⁹ found two *TGFBR1* and five *TGFBR2* mutations in 41 unrelated patients who did or did not fulfill the diagnostic criteria for MFS, in whom mutations in the *FBN1*-coding region were not identified; Stheneur *et al*¹⁰ found six mutations in the *TGFBR2* gene and one in the *TGFBR1* gene in 105 MFS patients, and nine mutations in the *TGFBR2* gene and two mutations in the *TGFBR1* gene in 247 patients with incomplete or probable MFS that were negative for a *FBN1* gene mutation. Chung *et al*¹¹ found six *TGFBR2* mutations in 41 MFS-like probands (previously negative for *FBN1*). None of these six patients with *TGFBR2* mutations fulfilled the clinical MFS criteria from the Ghent nosology.

TGFBR1/2 mutations have been described in familial thoracic aortic aneurysm families,^{4,5} but many of these families have not been evaluated in detail for clinical features that are common in LDS.

Finally, as stated above, some mutations have been described in Shprintzen-Goldberg syndrome, but these patients have features that are believed to be more common in LDS.⁶

No *TGFBR1/2* mutations have been found in families with presentation of isolated bicuspid aortic valve with or without aortic dilatation.¹²

2.5 Positive clinical predictive value (life-time risk to develop the disease if the test is positive)

Nearly 100%.

Incomplete penetrance,¹ as well as somatic mosaicism¹³ have been reported.

2.6 Negative clinical predictive value (probability not to develop the disease if the test is negative)

Assume an increased risk based on family history for a non-affected person. Allelic and locus heterogeneity may need to be considered.

Index case in that family had been tested:

Nearly 100%.

Index case in that family had not been tested:

Predictive testing for family members should only be proposed, if a pathogenic mutation has been identified in an index case.

3. CLINICAL UTILITY

3.1 (Differential) diagnosis: The tested person is clinically affected (To be answered if in 1.10 'A' was marked)

3.1.1 Can a diagnosis be made other than through a genetic test?

No	☐ (continue with 3.1.4)	
Yes	☒	
	Clinically	☒
	Imaging	☐
	Endoscopy	☐
	Biochemistry	☐
	Electrophysiology	☐
	Other (please describe)	Autopsy and histological verification of the typical findings are reasonable.

3.1.2 Describe the burden of alternative diagnostic methods to the patient

Physical exam, cardiological (including echocardiography) and vascular investigations (3D-CTscan or MR angiography) can altogether establish a diagnosis (but not always). These investigations are always necessary to evaluate the phenotype of the patient, which indicates the severity of the prognosis and guide therapy.

3.1.3 How is the cost effectiveness of alternative diagnostic methods to be judged?

Unknown.

3.1.4 Will disease management be influenced by the result of a genetic test?

No ☐

Yes ☒

Therapy (please describe) Regular and frequent cardiovascular follow-up and early surgery with aortic root replacement are mandatory. For young children with severe systemic findings of LDS, surgical repair of the ascending aorta should be considered early once the maximal dimension allows the placement of a graft of sufficient size to accommodate growth. Timing for surgery will always depend not only on the presence of *TGFBR* mutation, but also on the severity of the phenotype and family history. For adolescents and adults severely affected, some authors recommend surgical repair of the ascending aorta to be considered earlier than in classical MFS, such as an aortic diameter of 40 mm². This recommendation is based on examples of documented aortic dissection in adults with aortic root dimensions at or below 4.0 cm and the excellent response to prophylactic surgery. However, series report excellent prognosis when aortic root surgery is carried out above 50 mm, in adult patients presenting less severe phenotype.¹⁴ During pregnancy there is a risk for visceral rupture, ante- or post-partum hemorrhage and poor wound healing. Frequent monitoring of the aorta is essential for pregnant woman, and cervical instability should be excluded in the event that a general anaesthetic and caesarean section is required. Referral to a high-risk obstetric management clinic and delivery in a large tertiary referral centre is recommended. Prenatal diagnosis or, in some countries, preimplantation genetic diagnosis is possible, if the disease causing mutation is known.

Prognosis (please describe) There is evidence that patients with *TGFBR1/2* mutation need more extensive imaging of the aorta, and in some series, have increased risk for dissection at smaller aortic diameters than patients with classic MFS.² Therefore, identification of *TGFBR1/2* mutation could influence prognosis.

Management (please describe) Management should be coordinated in multidisciplinary clinic, experienced in the management of aortic aneurysm syndromes. Important considerations when managing cardiovascular features of Loeys-Dietz syndrome are:

- Aortic dissection may occur at smaller aortic diameters than observed in Marfan syndrome in severe phenotype
- Vascular disease may not be limited to the aortic root
- Beta-adrenergic blockers or other medications are used to reduce hemodynamic stress
- Aneurysms are amenable to surgical intervention.

Surgical fixation of cervical spine instability may be necessary to prevent spinal cord damage. Clubfeet and severe pes planus are treated in by standard protocols. Treatment of cleft palate and craniosynostosis is by standard protocols; management by a craniofacial team is preferred.

3.2 Predictive setting: The tested person is clinically unaffected but carries an increased risk based on family history
(To be answered if in 1.10 'B' was marked)

3.2.1 Will the result of a genetic test influence lifestyle and prevention?

If the test result is positive (please describe):

Yes.

All individuals with LDS require echocardiography at frequent intervals to monitor the status of the ascending aorta (usually yearly, but depending on the severity of the phenotype); the frequency of magnetic resonance angiography (MRA) or computerized tomography angiography (CTA) evaluations depend on clinical findings. Individuals with cervical spine instability and severe or progressive scoliosis should be followed by an orthopedic surgeon.

Contact sports, competitive sports, isometric exercise, agents that stimulate the cardiovascular system including routine use of decongestants should be avoided, as well as activities that cause joint injury or pain.

If the test result is negative (please describe):

Follow-up is dispensable and restriction of sports is unnecessary, if a familial mutation can be excluded. A negative result should be interpreted with care, if the mutation is unknown in the index patient. Testing for mutation in other genes should be considered, depending on the phenotype (*FBN1*, *ACTA2* and *MYH11*).

3.2.2 Which options in view of lifestyle and prevention does a person at-risk have if no genetic test has been done (please describe)?

Regular clinical follow-up similar to those with a mutation identified. Limitation of sports, beta-blockade are indicated depending on the confidence of the clinical diagnosis or evaluated aortic risk.

3.3 Genetic risk assessment in family members of a diseased person
(To be answered if in 1.10 'C' was marked)

3.3.1 Does the result of a genetic test resolve the genetic situation in that family?

Yes.

3.3.2 Can a genetic test in the index patient save genetic or other tests in family members?

Yes.

3.3.3 Does a positive genetic test result in the index patient enable a predictive test in a family member?

Yes.

3.4 Prenatal diagnosis

(To be answered if in 1.10 'D' was marked)

3.4.1 Does a positive genetic test result in the index patient enable a prenatal diagnostic?

Yes.

4. IF APPLICABLE, FURTHER CONSEQUENCES OF TESTING

Please assume that the result of a genetic test has no immediate medical consequences. Is there any evidence that a genetic test is nevertheless useful for the patient or his/her relatives? (Please describe)

Yes, other diagnostic testing becomes unnecessary. Patients and parents of affected children are usually relieved that the disease has been identified ('received a name'). They can seek contact with other persons affected by this disease through patient organization, which is usually seen as an enormous help in coping with the condition.

Genetic testing also allows early recognition of affected members who may benefit from preventive medical/surgical care due to wide intrafamilial variability.

Lastly, a negative test is very useful for the patient and their children as it removes the aortic threat, and abolishes needs for medical care and follow-up.

CONFLICT OF INTEREST

The authors declare no conflict of interest.
