Calculating the error in refractive error

RH Taylor¹, RB Ellingham¹, S Subramaniam²
 and LA Wakely³

Abstract

Aims and Purpose To demonstrate a quick way of calculating the optical difference between two refractions using vector analysis, and to express this as a score for examination purposes.

Methods An existing formula is applied, converted to a defocus equivalent, and then converted to a score. The formula is set out in an Excel spreadsheet.

Results The spreadsheet enabled rapid assessment of the difference between two refractive errors. Examples are demonstrated.

Conclusion The spreadsheet was successful in enabling a comparison of any two refractions, expressing the difference either as a correcting (third) refraction, a defocus equivalent or a one-figure score.

Eye (2011) 25, 1333–1336; doi:10.1038/eye.2011.169; published online 22 July 2011

Keywords: vector analysis; refraction; spherocylinder

Introduction

We wished to assign an error score to the candidates who were taking their examination in refraction, based on the refraction they prescribed compared with the correct refraction. We wanted a quick and easy way to enter data and produce error scores in a busy exam setting.

Before we settled on the method devised and outlined below, the following problems had to be overcome. First, two different refractions could have the same spherical equivalent. Second, if marks were to be awarded for correct cylinder power and axis, difficulty would be encountered if one of the refractions were a sphere. Lastly, there would be a difficulty if the marking scheme was influenced by positive and negative cylinder format.

Methods

Vector analysis was used to calculate a correcting refraction, which converts the

incorrect refraction to the correct one. These calculations have previously been published by Retzlaff *et al.*¹

The correcting refraction then required conversion to a score. We decided to use a second formula, published by Holladay,² to calculate the defocus equivalent. This would give an error value in dioptres. This method was chosen as the value (in dioptres) has been shown to correlate with loss of uncorrected visual acuity, resultant from the induced refractive error.

The resultant error in dioptres can be converted to a mark. The mark would depend on the total number of marks available for that question and would, therefore, vary between questions.

Lastly, the process for generating marks had to be in a format that could be used rapidly. This was carried out using an Excel spreadsheet, which reproduced the calculations for every candidate at each station. The result for an average sitting of the examination would be a spreadsheet with ~500 rows, one row per candidate-refraction.

A spreadsheet was set up with cells available for the correct refraction for each question (as written by the examiner) and the candidates' measured refractions. Of interest was the spherical equivalent of each, which was calculated for comparison. In the examples given the cells are designated to row 1, and are shown in bold.

Cell A = OSCE name, candidate name	
Cell B = Correct sphere	[sph1]
Cell C = Correct cylinder power	[cylpwr1]
Cell D = Correct axis (in degrees)	[axis1]
Cell E = Correct spherical equivalent	= B1 + (C1/2)
Cell F = Candidate measured sphere	[sph3]
Cell G = Candidate measured cylinder power	[cylpwr3]
Cell H = Candidate measured axis (degrees)	[axis3]
Cell I = Candidate measured spherical equivalent	= F1 + (G1/2)

The axis (in degrees) was converted to radians, which is required for the formula:

Cell J = Correct axis (in radians) = RADIANS(D1)
 Cell K = Candidate measured axis (in radians) = RADIANS(H1)
 Cell L = Expresses 0 degrees in radians (see Q1) = RADIANS(0)

At this point the spreadsheet applies step 1–4 of the formula as outlined by Retzlaff *et al*¹ for subtracting spherocylinders:

$$\text{sph3/cylpwr3} \times \text{axis3} - \text{sph1/cylpwr1} \times \text{axis1} = \text{sph2/cylpwr2} \times \text{axis2}$$

Step 1: finds the vectors of the cylinders of the two known refractions.

Cell M = Expresses X1 = cylpwr1 $\times$ cos(2 $\times$ axis1) = C1*COS(2*J1)
 Cell N = Expresses Y1 = cylpwr1 $\times$ sin(2 $\times$ axis1) = C1*SIN(2*J1)
 Cell O = Expresses X3 = cylpwr3 $\times$ cos(2 $\times$ axis3) = G1*COS(2*K1)
 Cell P = Expresses Y3 = cylpwr3 $\times$ sin(2 $\times$ axis3) = G1*SIN(2*K1)

Step 2: determines the axis of the new refraction (in radians).

Cell Q: IF M = O, Cell Q reads for Cell L (ie, 0 degrees in radians)

$$\text{Otherwise: } (\arctan[(Y3 - Y1)/(X3 - X1)]) / 2 \\ = \text{IF}(M1 = O1, L1, (\text{ATAN}((P1 - N1)/(O1 - M1))) / 2)$$

Step 2 needs to exclude the possibility of X3 = X1, because if so, the fraction fails as the denominator is zero. Therefore, if this event occurs, the formula for Cell Q expresses Cell L first. This only happens when the cylinder and power are identical—making the correcting refraction a sphere. The axis of a cylinder of no power is irrelevant; however, we have to put in a figure, so we used the axis zero.

Cell R: Expresses Cell Q in degrees (this may be a negative number)

$$= \text{DEGREES}(Q1)$$

Cell W: is used to eliminate a negative number in cell R

$$= \text{IF}(R1 < 0, R1 + 180, R1)$$

Step 3: determines the cylinder power of the correcting refraction, in dioptres.

$$\text{Cell S: } \text{cylpwr2} = [\text{cylpwr3} \times (\cos(2 \times (\text{axis3} - \text{axis2}))) - \\ [\text{cylpwr1} \times (\cos(2 \times (\text{axis1} - \text{axis2})))] \\ = (G1 * (\text{COS}(2 * (K1 - Q1)))) - (C1 * (\text{COS}(2 * (J1 - Q1))))$$

Step 4: determines the resultant sphere power of the correcting refraction, in dioptres.

$$\text{Cell T: } \text{sph2} = \text{sph3} - \text{sph1} - 0.5 \times (\text{cylpwr1} + \text{cylpwr2} - \text{cylpwr3}) \\ = F1 - B1 - (0.5 * (C1 + S1 - G1))$$

At this point the four steps as outlined by Retzlaff¹ have calculated a new correcting refraction from the candidate's one to the correct one. For convenience this is realigned in a more conventional way:

$$\text{Cell U} = \text{Cell T}$$

$$\text{Cell V} = \text{Cell S}$$

$$\text{Cell W} = \text{IF}(R1 < 0, R1 + 180, R1) \text{ (as already explained)}$$

Step 5: calculates the defocus equivalent as published by Holladay.²

Cell X: calculates the Spherical Equivalent of the correcting refraction

$$= U1 + (V1/2)$$

Cell Y: converts the spherical equivalent of the correcting refraction to a positive number if it is negative

$$= \text{SQRT}(X1 * X1)$$

Cell Z: converts the calculated cylindrical error to a positive number if it is negative

$$= \text{SQRT}(V1 * V1)$$

Cell AA: calculates the defocus equivalent

$$= (Y1 + Z1/2)$$

This now produces one figure—the defocus equivalent (DFE)—which represents the error between the two refractions, in dioptres. This is now used to calculate a mark, which could vary depending on the question, the total marks available and how accurate you are expecting the refraction to be. Below is one example marked out of 12.

Step 6:

$$\text{CellAB: converts the defocus equivalent into a mark} \\ = \text{IF}(AA1 < 0.25, 12, \text{IF}(AA1 < 0.51, 11, + \text{IF}(AA1 < 0.76, 10, + \text{IF}(AA1 < 1.01, 9, + \text{IF}(AA1 < 1.12, 8, + \text{IF}(AA1 < 1.25, 7, + \text{IF}(AA1 < 1.5, 6, + \text{IF}(AA1 < 1.75, 5, + \text{IF}(AA1 < 2, 4, + \text{IF}(AA1 < 2.5, 3, + \text{IF}(AA1 < 3, 2, + \text{IF}(AA1 < 4, 1, + \text{IF}(AA1 > 4, 0))))))))))$$

Note Excel versions 2003 and earlier may not support greater than six + IF logical tests.

Results

We present several examples that were problematic using any other system. Table 1 shows different refractions with the same spherical equivalent. In the first four rows, the candidate has chosen to use a positive cylinder, and in the second four rows a negative cylinder is used. As can be observed, the results are not different when refractions are written in different formats.

Table 2 addresses the problem encountered when one refraction is a sphere and the other has a cylinder.

In Table 3, if the cylinder axis alone is incorrect, sensible marks are generated relative to cylinder power.

In Table 4, if the power of the cylinder and axis require no change, only the spherical change is calculated and marked accordingly.

Finally, Table 5 shows that the equation is stable over a wide range of mixed astigmatism.

Discussion

This spreadsheet application has enabled the rapid assessment of the error between two refractions. This has been used already in the Refraction Certificate examination for the FRCOphth to calculate error between

two refractive errors, allowing this to be carried out in real time during the exam sitting.

This method will have other uses for studying the induced refractive error following surgical procedures

Summary

What was known before

- It was known that it is possible to measure refraction using vector analysis, and also possible to deduce the difference between any two refractions.

What this study adds

- This study takes what was known and describes processing this using an Excel spreadsheet to enable rapid assessment of the difference between two refractions.
 - We also use the spreadsheet to deduce a defocus equivalent of the correcting refraction.
 - This is then used to calculate a one-figure measure of this defocus equivalent.
-

such as cataract surgery, corneal suture placement or removal and astigmatic corneal surgery.

Notes

The equation used to generate a mark is used for illustration purposes only and does not represent any equation currently in use.

Conflict of interest

The authors declare no conflict of interest.
