

look about them. To many readers, however, Professor Harris' review of the present position of human biochemical genetics will be an equal, perhaps even greater, attraction. It is wide ranging, covering the hæmoglobin and haptoglobin polymorphisms as well as biochemical disorders in a very informative way, with an extensive list of references. It provides a most useful summary of the present situations in this branch of genetics and one which the non-specialist will find eminently readable. We are indebted to Professor Harris for this publication.

KENNETH MATHER.

EVOLUTION: THE MODERN SYNTHESIS. By Julian Huxley. Second edition. Allen & Urwin, London. 1963. Pp. li+652. Price 42s.

First published in 1942 Huxley's "Evolution" is now a standard book of reference. As the author points out, however, an enormous volume of new work and new ideas has appeared in the past twenty years. In addition, therefore, to the original text (of which this is the seventh impression) this new edition includes a special introduction which occupies 39 pages and which touches on the most important developments that have taken place in the study of evolution. A supplementary biography is also added.
