#### Abstract

Antimycin $\mathrm{A}_{9}\left(\mathrm{AA}_{9}\right)$ isolated from a cultured broth of Streptomyces sp. K01-0031 was synthesized via an asymmetric aldol reaction using Oppolzer's sultam as a chiral auxiliary.

Keywords asymmetric synthesis, asymmetric aldol reaction, antimycin $\mathrm{A}_{9}$, antibiotics

The antimycin A (AA) family isolated from Streptomyces sp. possesses significant biological activities [1], such as antifungal, insecticidal, and anticancer, as well as an inhibitory activity against ubiquinol-cytochrome $c$ oxidoreductase. Among the AA family, $\mathrm{AA}_{3}$ is one of the most active agents and has been widely used in biological and biochemical studies. On the contrary, $(+)-\mathrm{AA}_{9}$ (Figure 1) recently isolated from a cultured broth of Streptomyces sp. K01-0031 together ${A A_{3 a}}^{2}, \mathrm{AA}_{3 \mathrm{~b}}, \mathrm{AA}_{4}$, and $\mathrm{AA}_{7}$ by Kitasato's groups showed more potent nematocidal and insecticidal activities against Caenorhaditis elegans and Artemia salina than other known antimycins [1b]. Thus, involving the discovery of new compounds, investigation of the AA family is still continued because of their characteristic biological activities. For precise biological and biochemical investigations, the supply of each pure component of the AA family seems to be very important. However, since the isolation of each pure component from a cultured broth is possible only with intensive effort [2], the pure material of each component is not practically available for biological and biochemical studies. Therefore,

the Antimycin A complex (mixture of AA family purchased from Sigma Co.) was used in most biological and biochemical studies.

Due to their outstanding bioactivities and unique structures, the antimycin family has attracted much interest from synthetic organic chemists [3]. Up to now three groups accomplished enantioselective total synthesis of $\mathrm{AA}_{3 \mathrm{~b}}$ (previous name $\mathrm{AA}_{3}$ ) $[3 \mathrm{~b} \sim \mathrm{e}]$. However, the synthesis of other antimycins has not been performed and further effort directed to a practical and economical synthesis is still needed to supply sufficient amounts of pure antimycins for the biological investigations.

In the previous paper, we reported the synthesis of $(+)-$ $\mathrm{AA}_{3 \mathrm{a}}$ and $(+)-\mathrm{AA}_{3 \mathrm{~b}}$ using an asymmetric aza-Claisen rearrangement, although the overall yield was low [3c, d]. To develop a practical synthetic route of antimycins, we reconsidered the synthetic route and found that an asymmetric aldol reaction using Oppolzer's sultam as a chiral auxiliary was quite effective to construct the C-7 and C-8 asymmetric centers. Utilizing this methodology, we performed the first and efficient synthesis of $(+)-\mathrm{AA}_{9}$, which is the first antimycin having an aromatic 8 -acyl residue. The results are reported herein.

Sultam amide 2 reacted with aldehyde $\mathbf{3}$ under the modified [4] Oppolzer's conditions to give the desired aldol adduct 4 and its stereoisomer [5] in $82 \%$ yield (ratio $=98 / 2$ )

[6]. The best results were obtained with 1.5 equivalents of dibutylboron trifluoromethanesulfonate ( $n$ - $\mathrm{Bu}_{2} \mathrm{BOTf}$ ), 2.0 equivalents of diisopropylethylamine (DIPEA), and 2.5 equivalents of 3 . The pure $4(>99 \%$ de) afforded by recrystallization ( $63 \%$ isolated yield) was converted to allyl ester 5 by heating at $150^{\circ} \mathrm{C}$ with allyl alcohol in the presence of titanium isopropoxide $\left[\mathrm{Ti}(\mathrm{O}-i \mathrm{Pr})_{4}\right]$ and molecular sieves $4 \AA$ (MS 4A) (74\%) [7].

After protection of the hydroxy group by triisopropylsilyl (TIPS) group, the $p$-methoxyphenylmethyl (MPM) group was removed with 2,3-dichloro-5,6-dicyano-1,4benzoquinone (DDQ) to yield alcohol 7. Condensation of 7 with L-threonine derivative 8 [8] proceeded satisfactorily under Yamaguchi conditions to give 9 in $84 \%$ yield (2 steps) [9]. Removal of the TBS group with 6 M HCl followed by palladium(0)-catalyzed deprotection $\left[\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}, \mathrm{PPh}_{3}\right.$, pyrrolidine] of the allyl ester provided the seco acid 10. Via conversion of $\mathbf{1 0}$ to the 2-pyridinethiol ester, lactonization was accomplished by heating at $80^{\circ} \mathrm{C}$ in toluene with copper(I) trifluoromethanesulfonate-benzene complex $\left[(\mathrm{CuOTf})_{2} \cdot \mathrm{PhH}\right]$ under high dilution conditions to give dilactone 11 in $79 \%$ yield (4 steps from 9) [10].

The TIPS group of lactone $\mathbf{1 1}$ was removed smoothly using hydrogen fluoride pyridine (HF-Py) at r.t. to provide alcohol 12 ( $98 \%$ yield), which was esterified with phenylacetic acid in the presence of $N$-(3-Dimethyl-aminopropyl)- $N^{\prime}$-ethylcarbodiimide hydrochloride [water-
soluble carbodiimide (WSC)] and 4-(N,N-dimethylamino)pyridine (DMAP) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ to provide ester $\mathbf{1 3}$ in excellent yield ( $92 \%$ ). The benzyloxycarbonyl (cbz) group of $\mathbf{1 3}$ was removed by hydrogenolysis (Pd-C in THF) to give an amine, which was successfully acylated with 14 (See the experimental section.), using WSC, 1-hydroxybenzotriazole hydrate (HOBt), and $N$-methylmorpholine (NMM) in DMF to give 15 . Removal of the benzyl protecting group of $\mathbf{1 5}$ by hydrogenolysis with Pd-C in ethyl acetate led cleanly to the target molecule ( + )-antimycin $\mathrm{A}_{9}(69 \%$ yield from 13), mp $151.0 \sim 152.0^{\circ} \mathrm{C},[\alpha]_{\mathrm{D}}^{22}+82.1$ (c $0.17, \mathrm{CH}_{3} \mathrm{OH}$ ), whose physical properties compared well with those in the literature $[1 \mathrm{~b}]\left[\mathrm{mp} 134 \sim 139^{\circ} \mathrm{C},[\alpha]_{\mathrm{D}}^{25}+83.6\right.$ (c 0.157 , $\left.\mathrm{CH}_{3} \mathrm{OH}\right)$ ].
Thus, the asymmetric aldol reaction using Oppolzer's sultam provided a practical and economical synthetic route ( 15 steps, overall yield $24 \%$ ) to $(+)$-antimycin $\mathrm{A}_{9}$, which could be obtained in pure form on a 300 mg scale in this synthesis. Further synthetic studies of not only the AA family but also their analogs and investigation of their biological activities are now in progress.

## Antimycin $\mathbf{A}_{9}$

A mixture of $\mathbf{1 5}(358 \mathrm{mg}, 0.56 \mathrm{mmol})$ and $\mathrm{Pd} / \mathrm{C}$ (catalytic amount) in EtOAc ( 3 ml ) was stirred under $\mathrm{H}_{2}$ atmosphere for 2 hours. The mixture was filtered through a pad of Celite, and the filtrate was concentrated. The residue ( 295 mg ) was purified by silica gel column chromatography (hexane/EtOAc) to give antimycin $\mathrm{A}_{9}(284 \mathrm{mg}, 89 \%)$ as a pale yellow solid (rotamer mixture); mp $151.0 \sim 152.0^{\circ} \mathrm{C}$; $[\alpha]_{\mathrm{D}}^{22}+82.1(c 0.17, \mathrm{MeOH}) ;$ IR (ATR) $\mathrm{cm}^{-1}: 3372,2957$, 2872, 2360, 2341, 1745, 1530, 1364, 1182; ${ }^{1} \mathrm{H}$ NMR $\left(600 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 12.61$ and 12.47 (total integr. 1 H , s and s), 8.09 and 8.50 (total integr. $1 \mathrm{H}, \mathrm{d}, J=11.0 \mathrm{~Hz}$ and brs ), $8.55(1 \mathrm{H}, \mathrm{d}, J=10.2 \mathrm{~Hz}), 8.11$ and 7.83 (total integr. 1 H , brs and brd, $J=10.2 \mathrm{~Hz}), 7.32 \sim 7.38(2 \mathrm{H}, \mathrm{m})$, $7.26 \sim 7.32(3 \mathrm{H}, \mathrm{m}), 7.24(1 \mathrm{H}, \mathrm{dd}, J=8.0,0.8 \mathrm{~Hz}), 7.10$ and 6.91 (total integr. $1 \mathrm{H}, \mathrm{d}, J=7.7 \mathrm{~Hz}$ and d, $J=7.7 \mathrm{~Hz}$ ), 6.90 $(1 \mathrm{H}, \mathrm{t}, J=8.2 \mathrm{~Hz}), 5.75$ and 5.71 (total integr. $1 \mathrm{H}, \mathrm{q}$, $J=6.9 \mathrm{~Hz}$ and q, $J=7.1 \mathrm{~Hz}$ ), 5.32 and 5.27 (total integr. 1 H , $\mathrm{t}, J=7.7 \mathrm{~Hz}$ and $\mathrm{t}, J=7.4 \mathrm{~Hz}$ ), 5.09 and 5.05 (total integr. $1 \mathrm{H}, \mathrm{t}, J=10.2 \mathrm{~Hz}$ and $\mathrm{t}, J=10.2 \mathrm{~Hz}), 4.93(1 \mathrm{H}, \mathrm{dq}, J=6.6$, $6.3 \mathrm{~Hz}), 3.67(2 \mathrm{H}, \mathrm{s}), 2.49(1 \mathrm{H}, \mathrm{ddd}, J=13.2,10.2,2.7 \mathrm{~Hz})$,
