ORIGINAL ARTICLE

The vacuole-targeting fungicidal activity of amphotericin B against the pathogenic fungus *Candida albicans* and its enhancement by allicin

Hasibagan Borjihan¹, Akira Ogita^{1,2}, Ken-ichi Fujita¹, Eiji Hirasawa¹ and Toshio Tanaka¹

In this study, the vacuole disruptive activity was evaluated as a cause of amphotericin B (AmB) lethality against the pathogenic fungus *Candida albicans* in terms of its enhancement by allicin, an allyl-sulfur compound from garlic. Vacuole disruption was observed in parallel to AmB-induced cell death when the antibiotic was used at a lethal concentration and at a non-lethal concentration in combination with allicin. Allicin did not enhance AmB-induced cell death and the accompanying vacuole disruption when the cells were incubated with exogenous ergosterol for its enrichment in the vacuole. The vacuoles isolated from intact cells could be directly disrupted by the action of AmB to the same extent in the absence and presence of allicin, whereas the organelles isolated from ergosterol-enriched cells were resistant to its direct disruptive action. AmB was similarly incorporated into the fungal cytoplasm in cells with or without ergosterol enrichment, supporting the fact that AmB-induced vacuole disruption depends on its direct disruptive action on the organelle. In agreement with these findings, allicin was found to inhibit ergosterol transport from the plasma membrane to the cytoplasm, which is considered to be a cellular protective response to AmB-induced vacuole disruption in *S. cerevisiae*. Our study suggests that AmB lethality against *C. albicans* depends at least in part on its vacuole disruptive activity under the physiological condition permissive for invasive growth of the fungus.

INTRODUCTION

Candida albicans is a ubiquitous fungus, which is normally found on the skin, and also in the mouth, throat, stomach, rectum and vagina; this fungus causes candidiasis as a result of its proliferation in any of these mammalian organs.¹ Medical treatment for candidiasis includes chemotherapy using amphotericin B (AmB; Figure 1), a typical polyene macrolide antibiotic that is derived from the actinomycete *Streptomyces nodosus*.^{2,3} AmB binds to ergosterol in the fungal plasma membrane and induces lethal damage by altering plasma membrane permeability.⁴ However, the AmB-induced lethal damage cannot be simply explained by the disturbance in plasma membrane ion transfer function because the leakage of K⁺ results in various secondary effects, including the inhibition of protein synthesis.⁵ Moreover, the involvement of additional cytotoxic effects in AmB lethality is supported by the fact that the leakage of K⁺ is not necessarily accompanied by the loss of cell viability in *C. albicans*.⁶ Oxidative stress induction is considered to be another AmB-induced toxic event in the cells of this pathogenic fungus.^{2,7} In our recent study, we observed vacuole membrane fragmentation in *Saccharomyces cerevisiae* cells on incubation

with AmB in distilled water, in which the organelle actively functions for cellular ion homeostasis and osmoregulation.⁸ In addition to the alteration in plasma membrane permeability in *S. cerevisiae*, AmB lethality could be attributed, at least in part, to its direct disruptive action on vacuoles.

Allicin (diallyl thiosulfinate) (Figure 1) exerts various therapeutic effects that could be applicable for protection against the proliferation of pathogenic microbes as well as malignant tumor cells.^{9,10} This allyl-sulfur compound is also of clinical interest because of its beneficial effects on neutral lipid metabolism and its inhibitory effect on platelet aggregation.^{11,12} We recently reported its enhancement effect on the fungicidal activities of AmB and polymyxin B (PMB), which is a bactericidal antibiotic, against various fungal strains.^{8,13,14} Allicin selectively enhanced the vacuole disruptive activity but not the plasma membrane-targeting activity of these antibiotics against *S. cerevisiae*. The enhancement effect of allicin on AmB lethality could be elucidated by its inhibitory effect on ergosterol transport from the plasma membrane to the vacuole membrane that occurs as a cellular response to protect against the direct disruptive action of the antibiotic on the

organelle.¹⁵ In a recent study, it was proposed that allicin could be used to enhance AmB lethality against *C. albicans* on the basis of the *in vivo* experiment conducted using a murine model of candidiasis.¹⁶ They also proposed that plasma membrane phospholipid peroxidation, which is slightly provoked by the action of AmB alone and is markedly enhanced by the combined actions of AmB and allicin, is the most promising effect of allicin as an AmB enhancer. However, because their *in vitro* experiment, as in the case of our study, was conducted in distilled water or mineral salt medium at 30 °C, further studies are required to determine whether the enhancement effect of allicin indeed depends on such a cell surface oxidative event *in vivo*.

In this study, we attempted to examine the enhancement effect of allicin on the fungicidal activity of AmB against *C. albicans* cells in RPMI 1640 medium at 37 °C. We focused our attention on vacuole disruption as well as oxidative stress induction during the course of cell death caused by the combined actions of AmB and allicin. We also examined the mechanism underlying the enhancement effect of allicin on one of these toxic events in *C. albicans* cells by using methods described in our previous experiments with *S. cerevisiae*.

MATERIALS AND METHODS

Measurement of cell growth and viability

C. albicans NBRC 1061 (formerly *C. albicans* IFO 1061) was used in the following experiments to examine the effects of AmB and allicin on cell growth, cell viability and other physiological properties.⁸ The fungal cells were pre-cultivated in YPD medium containing 1% yeast extract (Difco Laboratories, Detroit, MI, USA), 2% Bacto-peptone (Difco Laboratories) and 2% glucose at 30 °C with vigorous shaking. Unless otherwise stated, cells from the overnight culture in YPD medium were collected by centrifugation, washed twice with RPMI 1640 medium with L-glutamine¹⁷ (RPMI 1640 medium) and suspended in the medium to obtain a final cell density of 1×10^7 cells ml⁻¹. Cells were then incubated in the absence and presence of each compound with vigorous shaking at 37 °C. Viable cell number was determined by counting colony forming units after 24-h incubation on YPD agar plate at 30 °C.⁸

Vacuole staining

Vacuoles were visualized by staining with the fluorescent probe FM4-64 as follows.⁸ Cells from the overnight culture in YPD medium were suspended in a freshly prepared medium to obtain a cell density of 1×10^7 cells ml⁻¹. After incubation with 5 μM FM4-64 at 30 °C for 30 min, the cells were collected by centrifugation, washed twice with RPMI 1640 medium and suspended in the medium at a final cell density of 1×10^7 cells ml⁻¹. The cells were incubated in the absence and presence of each compound with vigorous shaking at 37 °C for 60 min, and were then observed under a phase-contrast microscope and a fluorescence microscope with excitation at 520–550 nm and emission at 580 nm.

Vacuole isolation

The vacuoles were isolated from *C. albicans* cells by using previously described methods^{18–20} with slight modifications¹⁵ as follows. Cells from the overnight culture in YPD medium were collected by centrifugation and suspended in spheroplasting buffer (50 mM Tris-HCl, pH 7.5; 1 M sorbitol; 10 mM sodium azide) with 0.5% 2-mercaptoethanol to obtain a cell density of 1×10^9 cells ml⁻¹. After the addition of Yeast Lytic Enzyme at 6 mg ml⁻¹, the cells were converted to spheroplasts by incubation at 30 °C for 60 min. The spheroplasts were then collected by centrifugation, washed with vacuole isolation buffer (10 mM sodium citrate, pH 6.8; 0.6 M sorbitol) and carefully suspended in the buffer at a final density of 5×10^9 cells ml⁻¹. All the subsequent procedures were carried out on ice. The spheroplasts were homogenized with 20 strokes of a Dounce homogenizer. The homogenate (15 ml) was transferred into a centrifugation tube and was gently overlaid first with 10 ml of vacuole isolation buffer containing 7% Ficoll and next with 10 ml of the buffer containing 8% Ficoll. After centrifugation (3000 g) at 4 °C for 30 min, the vacuoles at the 7–0% Ficoll interface were collected.

Assay of reactive oxygen species production

The production of reactive oxygen species (ROS) such as O₂⁻ and H₂O₂ was determined by our previously described method based on the intracellular deacylation and oxidation of 2',7'-dichlorodihydrofluorescein diacetate (DCFH-DA) to the corresponding fluorescent compound.²¹ Isoprenoid farnesol (FOH) was used as a positive control to enhance intracellular ROS production. Cells from the overnight culture in YPD medium were collected by centrifugation, suspended in the medium to obtain a cell density of 1×10^7 cells ml⁻¹ and incubated with 40 μM DCFH-DA at 30 °C for 60 min. The cells were then collected by centrifugation and suspended in an equal volume of RPMI 1640 medium. The cell suspension (1.0 ml) was further incubated in the absence and presence of each compound at 37 °C for 120 min. The cells were collected by centrifugation, washed with phosphate-buffered saline (137 mM NaCl, 8.1 mM Na₂HPO₄·12H₂O, 2.68 mM KCl, 1.47 mM KH₂PO₄, pH 7.4) (PBS) and suspended in 100 μl of PBS. The fluorescence intensities of the cell samples (1×10^7 cells) were measured using the Tecan GENios fluorescence detector (Männedorf, Switzerland) at excitation and emission wavelengths of 480 and 530 nm, respectively. The arbitrary units were derived directly from the fluorescence intensity.

Assay of plasma membrane phospholipid peroxidation

The extent of plasma membrane phospholipid peroxidation was determined using a fluorescence probe, diphenyl-1-pyrenylphosphine (DPPP) and *t*-butyl hydroperoxide (*t*-BOOH) as a positive control as follows.²² Cells from the overnight culture in YPD medium were collected by centrifugation, washed with PBS and suspended in PBS at a final cell density of 3×10^7 cells ml⁻¹. After the addition of DPPP at a concentration of 50 μM and incubation for 10 min in the dark, the cells were collected by centrifugation, washed twice with PBS and finally suspended in RPMI 1640 medium at a final cell density of 1×10^7 cells ml⁻¹. The cell suspension was further incubated in the absence and presence of each compound at 37 °C for 120 min. The fluorescence intensities of the cell samples (1×10^6 cells) were measured using the FP-1520S fluorescence detector (Jasco, Tokyo, Japan) at excitation and emission wavelengths of 351 and 380 nm, respectively. The arbitrary units were derived directly from the fluorescence intensity.

Measurement of AmB content by HPLC

Cells from the overnight culture in YPD medium were collected by centrifugation, washed twice with PBS and suspended in PBS to obtain a final cell density of 1×10^8 cells ml⁻¹. The cell suspension in PBS was incubated with 20 μM AmB in the absence and presence of 120 μM allicin at 37 °C for 60 min. The supernatant obtained after the removal of cells by centrifugation was used as the supernatant fraction. The cell pellets were washed twice with PBS by repeated centrifugation and then suspended in PBS at a cell density of 1×10^8 cells ml⁻¹; the cells were incubated after the addition of Yeast Lytic Enzyme at a final concentration of 6 mg ml⁻¹ and 0.5% 2-mercaptoethanol at 30 °C with gentle agitation for 60 min or longer to ensure complete cell lysis. The supernatant obtained after centrifugation (5000 g, 10 min, 4 °C) of the cell

lysate was used as the cytoplasmic fraction. The pellets were washed twice with PBS by repeated centrifugation, and the final precipitate obtained (plasma membrane phospholipids) was decomposed by repeated vortexing with a mixture of water/methanol/chloroform (30:20:50, v/v) at room temperature. The upper water-soluble layer was used as the plasma membrane fraction.

These fractions were assayed for AmB content by HPLC with a reverse-phase column (4.6 by 250 mm, COSMOSIL 5C₁₈-MS-II, Nacalai Tesque Inc., Kyoto, Japan). The chromatographic solvents were eluted at room temperature with a mobile phase consisting of a mixture of 0.1 M sodium acetate (pH 4.0)/acetonitrile (60:40, v/v) at a flow rate of 1.2 ml min⁻¹. AmB was detected at 405 nm.²³

Detection of ergosterol

The subcellular localization of ergosterol was analyzed by its visualization with filipin III as a selective fluorescent probe according to the previously described method.¹⁵ Cells from the overnight culture in YPD medium were collected by centrifugation, washed twice with RPMI 1640 medium and suspended in the medium to obtain a final cell density of 1×10^7 cells ml⁻¹. Cells were then incubated in the absence and presence of each compound with vigorous shaking at 37 °C, and fixed with the addition of 3% paraformaldehyde at room temperature for 10 min. The fixed cells were collected by centrifugation, washed with distilled water and incubated in the dark with 50 µg ml⁻¹ filipin III at 30 °C for 15 min. Cells were then observed under a phase-contrast microscope and a fluorescence microscope with excitation at 338 nm and emission at 480 nm.

Preparation of ergosterol-enriched cells

For measurement of cell growth and vacuole staining, cells from the overnight culture in YPD medium were inoculated into a freshly prepared YPD medium containing 240 µM ergosterol at a cell density of 1×10^7 cells ml⁻¹, and incubated with vigorous shaking at 30 °C for 60 min. For vacuole isolation, cells from the overnight culture in YPD medium were inoculated into a freshly prepared YPD medium containing 500 µM ergosterol at a cell density of 1×10^9 cells ml⁻¹, and incubated with vigorous shaking at 30 °C for 60 min. For HPLC-analysis of AmB, cells from the overnight culture in YPD medium were inoculated into a freshly prepared YPD medium containing 370 µM ergosterol at a cell density of 1×10^8 cells ml⁻¹, and incubated with vigorous shaking at 30 °C for 60 min. These ergosterol-enriched cells were treated exactly in the same way as untreated cells in each of the above experiments.

Chemicals

The chemicals were obtained from the following sources: AmB and filipin III, Sigma Aldrich (St Louis, MO, USA); allicin, LKT Laboratories Inc. (St Paul, MN, USA); FM4-64 and DCFH-DA, Molecular Probe (Eugene, OR, USA); DPPP, Dojindo (Kumamoto, Japan); Ficoll 400, Alfa Aesar (Ward Hill, MA, USA); Yeast Lytic Enzyme, ICN Biomedicals (Aurora, OH, USA). The other chemicals used were of analytical reagent grade and purity.

RESULTS

Enhancement effect of allicin on AmB lethality

We first examined whether allicin could enhance AmB lethality against *C. albicans* cells by determining the changes in cell viability. AmB showed a highly lethal effect at 2 µM and even at the non-lethal concentration of 0.25 µM in combination with 120 µM allicin (Figure 2); these lethal concentrations were comparable with the concentration that effectively induced cell death of *S. cerevisiae* in distilled water.⁸

Effects of AmB and allicin, and their combination on ROS production and plasma membrane phospholipid peroxidation

Allicin may not enhance AmB lethality by increasing AmB-induced oxidative stress in *C. albicans* cells in RPMI 1640 medium at 37 °C. As shown in Figure 3a, the level of ROS production was maintained at the control level when the cells were treated with allicin at 120 µM or AmB at the non-lethal concentration of 0.25 µM. We did not observe a

Figure 2 The effects of AmB on the viability of *C. albicans* cells in the absence (a) and presence of allicin (b). For (A), cells (1×10^7 cells ml⁻¹) were incubated in RPMI 1640 medium containing AmB at 0 µM (○), 0.25 µM (●) and 2 µM (□) at 37 °C. For (b), cells (1×10^7 cells ml⁻¹) were incubated in RPMI 1640 medium containing 120 µM allicin and AmB at 0 µM (○), 0.25 µM (●) and 2 µM (□) at 37 °C.

Figure 3 The effects of AmB, allicin and their combination on ROS production (a) and plasma membrane phospholipid peroxidation (b). For (a), cells (1×10^7 cells ml⁻¹) were incubated in RPMI 1640 medium containing none (1), 25 µM FOH (2), 120 µM allicin (3), 0.25 µM AmB (4) and a combination of 0.25 µM AmB and 120 µM allicin (5) at 37 °C for 120 min. For (b), cells (1×10^7 cells ml⁻¹) were incubated in RPMI 1640 medium containing none (1), 1 mM t-BOOH (2), 120 µM allicin (3), 0.25 µM AmB (4) and a combination of 0.25 µM AmB and 120 µM allicin (5) at 37 °C for 120 min. Data are expressed as the mean ± s.d. of the arbitrary units measured in triplicate assays, and are analyzed by Student's *t*-test. *P* < 0.05 is considered statistically significant.

significant difference in the level of ROS production when the cells were simultaneously treated with both AmB and allicin.

Allicin was found to accelerate plasma membrane phospholipid peroxidation in *S. cerevisiae* when the cells were incubated in distilled water at 30 °C.⁸ We therefore examined the relationship between plasma membrane phospholipid peroxidation and the enhancement effect of allicin on AmB lethality against *C. albicans* cells in RPMI 1640 medium at 37 °C. The levels of plasma membrane phospholipid peroxidation were not significantly increased when cells were incubated with either allicin or AmB alone at a non-lethal concentration (0.25 µM) (Figure 3b). Allicin was ineffective in increasing the level of such a cell surface oxidative event that was detected at the control level in AmB-treated cells. These results suggested the involvement of another toxic event in the enhancement effect of allicin on AmB lethality against *C. albicans* cells in RPMI 1640 medium at 37 °C.

Figure 4 The effects of AmB, allicin and their combination on vacuole morphology in *C. albicans* cells. After treatment with the fluorescent dye FM4-64, cells (1×10^7 cells ml^{-1}) were incubated in RPMI 1640 medium containing none (a), $120 \mu\text{M}$ allicin (b), $0.25 \mu\text{M}$ AmB (c), $2 \mu\text{M}$ AmB (d) and a combination of $0.25 \mu\text{M}$ AmB and $120 \mu\text{M}$ allicin (e) at 37°C for 60 min. Cells were observed under a bright-field microscope (top) and a fluorescence microscope (bottom).

Enhancement effect of allicin on vacuole disruption by AmB

Vacuole disruption was observed when *S. cerevisiae* cells were treated with a lethal concentration of AmB in distilled water in which cells are more susceptible to the lethal action of the antibiotic than in a medium.⁸ We therefore examined whether AmB treatment can trigger vacuole disruption in *C. albicans* cells maintained in RPMI 1640 medium at 37°C . The vacuoles appeared as membrane-enclosed spherical structures in untreated cells although they were smaller in size as compared with those in *S. cerevisiae* cells (Figure 4a). No morphological changes were observed in the organelles of the cells incubated in the medium containing $120 \mu\text{M}$ allicin (Figure 4b). Furthermore, AmB did not exert disruptive effects on the organelles at the non-lethal concentration ($0.25 \mu\text{M}$), but caused serious structural damages when administered at the lethal concentration ($2 \mu\text{M}$) (Figures 4c and d). In combination with allicin, AmB showed a similar vacuole disruptive activity even at non-lethal concentration ($0.25 \mu\text{M}$) in parallel to the enhancement of its lethality (Figures 2b and 4e).

Effects of allicin on AmB-induced cell death and vacuole disruption in ergosterol-enriched cells

Our previous study suggested that allicin inhibits ergosterol transport from the plasma membrane to the vacuole membrane when *S. cerevisiae* cells were treated with AmB in distilled water.¹⁵ Thus, ergosterol transport is considered to be a cellular response to protect the fungal vacuoles against the disruptive action of AmB. As observed in the case of *S. cerevisiae* cells, ergosterol-enriched *C. albicans* cells were completely resistant to the lethal effects of AmB at $2 \mu\text{M}$ or at $0.25 \mu\text{M}$ in combination with $120 \mu\text{M}$ allicin, though the fungal cell growth was inhibited under each of these conditions (Figure 5a). In agreement with the maintenance of cell viability, the vacuoles of ergosterol-enriched cells were observed to be normal spherical structures in the medium containing AmB at the lethal concentration ($2 \mu\text{M}$) and at a non-lethal concentration ($0.25 \mu\text{M}$) in combination with allicin (Figure 5b).

Direct disruption of isolated vacuoles by AmB

We examined whether AmB could directly disrupt the vacuoles isolated from *C. albicans* cells. The vacuoles isolated from intact cells were observed with the swollen spherical structures after incubation with $10 \mu\text{M}$ AmB, whereas the organelles were mostly disrupted into amorphous fragments or particles with increasing concentration of the antibiotic up to $20 \mu\text{M}$ (Figures 6a and c). Allicin did not

Figure 5 AmB-induced lethality (a) and vacuole disruption (b) in ergosterol-enriched *C. albicans* cells. For (a), ergosterol-enriched cells (1×10^7 cells ml^{-1}) were incubated in RPMI 1640 medium containing none ($\circ$), $2 \mu\text{M}$ AmB ($\bullet$), and a combination of $0.25 \mu\text{M}$ AmB and $120 \mu\text{M}$ allicin ($\square$) at 37°C . For (b), ergosterol-enriched cells (1×10^7 cells ml^{-1}) were incubated in RPMI 1640 medium containing $2 \mu\text{M}$ AmB (left) and a combination of $0.25 \mu\text{M}$ AmB and $120 \mu\text{M}$ allicin (right) at 37°C for 60 min. Cells were observed under a fluorescence microscope.

stimulate or inhibit AmB-induced vacuole disruption, indicating that this compound does not contribute to the direct interaction between the antibiotic and the fungal vacuole (Figures 6b and d). The vacuoles isolated from ergosterol-enriched cells were completely resistant to the disruptive action of $20 \mu\text{M}$ AmB both in the absence and presence of allicin. These findings agreed with our idea that allicin can enhance the fungicidal activity of AmB against *C. albicans* by inhibiting intracellular ergosterol transport, a cellular response to protect against vacuole disruption by AmB, as observed in the case of *S. cerevisiae*.¹⁵

Effect of allicin on cellular uptake of AmB

The enhancement effect of allicin on AmB-induced vacuole disruption also suggests that allicin enhances cellular uptake of the antibiotic into the cytoplasm of *C. albicans* cells via diffusion through the plasma membrane or a transporter-mediated incorporation. Ergosterol-enriched cells are likely to be more resistant to AmB than untreated cells because of its specific binding with ergosterol that may also be

Figure 6 The disruptive effects of AmB, allicin and their combination on isolated vacuoles obtained from *C. albicans* cells. Vacuoles from untreated (top) and ergosterol-enriched cells (bottom) were incubated with 10 μM (a, b) and 20 μM AmB (c, d), respectively, in the absence (a, c) and presence of 120 μM allicin (b, d) at 37 $^{\circ}\text{C}$ for 60 min. Vacuoles were observed under a bright-field microscope.

Table 1 Subcellular localization of AmB in *C. albicans* cells

Cells	Addition of allicin	AmB content (nmol) ^a in		
		Supernatant	Plasma membrane	Cytoplasm
Untreated	–	1.0 $\pm$ 0.2	16.2 $\pm$ 0.3	2.6 $\pm$ 0.3 ^b
	+	0.5 $\pm$ 0.2	16.1 $\pm$ 0.6	2.4 $\pm$ 0.2 ^b
Ergosterol-enriched	–	0.5 $\pm$ 0.1	16.5 $\pm$ 1.1	2.3 $\pm$ 0.2 ^b
	+	0.3 $\pm$ 0.1	16.7 $\pm$ 1.1	2.2 $\pm$ 0.2 ^b

Data are expressed as the mean $\pm$ s.d. of the AmB content in each fraction measured in triplicate assays. The AmB content of each cytoplasmic fraction is statistically analyzed by Student's *t*-test, in which $P < 0.05$ is considered statistically significant.

^aThe total quantity of AmB initially added to the assay mixture (1.0 ml) was 20 nmol.

^bNo significant difference between each of these values.

enriched in the plasma membrane. We thus examined the effects of allicin on subcellular localization of AmB by measuring its contents in various fractions obtained from untreated and ergosterol-enriched cells. In this experiment, the concentrations of AmB and allicin were increased up to 20 and 240 μM , respectively, with increasing cell density up to 1×10^8 cells ml^{-1} owing to the sensitivity of HPLC analysis. In untreated cells, AmB was mostly absent in the supernatant of the cell suspension when incubated with AmB alone for 60 min, and it was detected in the plasma membrane fraction at a ratio of more than 80% of the initial quantity that was added to the cells (Table 1). This can be explained by the binding of AmB to plasma membrane ergosterol. The remaining antibiotic was quantitatively recovered from the cytoplasmic fraction; this confirmed its penetration across the plasma membrane and into the cytoplasm. Apart from the finding that allicin enhanced AmB-induced vacuole disruption, this compound did not influence the subcellular localization of AmB. AmB penetrated into and across the plasma membrane of ergosterol-enriched cells as effectively as untreated cells, wherein its subcellular localization pattern remained unchanged both in the absence and presence of allicin.

Effect of allicin on subcellular localization of ergosterol

We finally confirmed the role of allicin in its enhancement effect on the fungicidal activity of AmB against *C. albicans* in terms of its effect

on subcellular localization of ergosterol. As shown in Figure 7, ergosterol was more brightly visualized in the plasma membrane than faintly stained cytoplasm of untreated cells, whereas this molecule was predominantly detected in the cytoplasm when cells are treated with AmB at a non-lethal concentration (Figures 7a and b). The intracellular localization of ergosterol was more clearly visualized in cells treated with AmB at a lethal concentration though its mobilization into the cytoplasm failed in protection against the vacuole disruption (Figure 7c). Ergosterol still remained in the plasma membrane when allicin was simultaneously added with AmB to enhance its vacuole-targeting fungicidal activity (Figure 7d).

DISCUSSION

It has been widely accepted that the fungicidal activity of AmB is a result of channel formation across the plasma membrane after the antibiotic selectively binds to ergosterol, thereby enhancing the leakage of intracellular K^+ and other ionic substances.^{2–4} Oxidative stress induction is also considered to be an AmB-induced cytotoxic event although it remains unclear whether this event is caused by auto-oxidation or the ionophoric property of the antibiotic.² We previously reported that allicin enhances the fungicidal activity of Cu^{2+} against *S. cerevisiae* in distilled water where the fungal cells are rendered extremely sensitive to this divalent cation.²⁴ Cu^{2+} -induced toxicity is characterized by intracellular ROS production, plasma membrane peroxidation and subsequent damage due to plasma membrane disruption, but the enhancement effect of allicin on this event was not simply elucidated by the enhancement of oxidative stress induction.²⁵ This also suggested the involvement of a lethal event other than plasma membrane phospholipid peroxidation in the enhancement effect of allicin on AmB lethality against *C. albicans*. On the other hand, An *et al.*¹⁶ attempted to use allicin in AmB-dependent chemotherapy for candidiasis, but insisted that allicin enhances AmB-induced plasma membrane phospholipid peroxidation in *C. albicans* cells. Unlike the case with its invasive growth in mammalian organs, however, the *in vitro* experiment in the above-mentioned study was conducted under a hypoosmotic condition where the metabolic pathways, which are usually not activated under the normal growth condition, may be activated in *C. albicans* cells. This study is thus expected to provide more reliable evidence of AmB lethality as well as its enhancement by allicin against *C. albicans* cells in RPMI 1640 medium at 37 $^{\circ}\text{C}$.

Figure 7 The effect of allicin on subcellular localization of ergosterol in *C. albicans* cells. Cells ($1 \times 10^7 \text{ ml}^{-1}$) were incubated in RPMI 1640 medium containing none (a), $0.25 \mu\text{M}$ AmB (b), $2 \mu\text{M}$ AmB (c) and a combination of $0.25 \mu\text{M}$ AmB and $120 \mu\text{M}$ allicin (d) at 37°C for 60 min. Cells were then fixed with 3% paraformaldehyde, incubated with $50 \mu\text{g ml}^{-1}$ filipin III, and observed under a phase-contrast microscope (top) and a fluorescence microscope (bottom).

Vacuoles are organelles that are involved in osmoregulation, ion homeostasis and cell volume regulation in fungal cells.^{26,27} Various hydrolytic enzymes, including proteases and nucleases, are thought to accumulate in vacuoles; hence, the damage to these organelles is considered to be a critical step in cell death induction.²⁸ In addition, the sudden loss of vacuoles would result in increased sensitivity to osmotic imbalance in the cytoplasm, especially in cells with impaired plasma membrane ion transport. Vacuole disruption was observed in *S. cerevisiae* cells treated with the polyene macrolide antibiotic niphimycin (NM) characterized by a macrocyclic lactone ring containing alkylguanidium.²⁹ A synthetic analog of this side chain could also render *S. cerevisiae* cells sensitive to the lethal effects of AmB, and this effect was indeed accompanied by enhanced vacuole disruption. PMB is a bactericidal antibiotic that can selectively inhibit the growth of Gram-negative bacteria by altering bacterial plasma membrane permeability and is weakly effective against fungal strains such as *S. cerevisiae*.^{13,14} Alternatively, allicin can enhance the fungicidal activity of PMB against *S. cerevisiae* and other fungal strains, including filamentous fungi such as *Aspergillus fumigatus*.¹³ The enhancement of the fungicidal activity of PMB by allicin was accompanied by enhanced vacuole disruption. As deduced from the similarity in the modes of action of AmB, niphimycin and PMB on ion transport through the plasma membrane, the vacuole disruptive activities of these antibiotics are likely to depend on cellular osmotic imbalance because of the leakage of K^+ in addition to their direct disruptive actions on the organelles. To our knowledge, this study is the first of its kind to reveal that enhanced vacuole disruption induced by AmB at a lethal concentration ($2 \mu\text{M}$) and at a non-lethal concentration ($0.25 \mu\text{M}$) in combination with allicin could be lethal against the pathogenic fungus *C. albicans*.

The vacuoles isolated from *C. albicans* cells are subjected to the direct disruptive action of the antibiotic at the lower concentration than is needed for disruption of the organelles from *S. cerevisiae* cells. However, there has been no clear evidence on the cellular uptake of AmB across the plasma membrane and into the cytoplasm. Although the enhancement of AmB-induced vacuole disruption by allicin is independent of this process, we for the first time demonstrated the accumulation of AmB in the cytoplasm of *C. albicans* cells. The AmB resistance of the ergosterol-enriched cells could therefore be attributed to the elevated resistance of the ergosterol-enriched vacuole rather

than an increase in the ergosterol content of the plasma membrane. In spite of such evidence that supports the direct interaction between AmB and the vacuoles, the concentration of AmB required for the direct disruptive action on the organelles ($20 \mu\text{M}$) was apparently higher than the extracellular concentration that resulted in vacuole disruption ($2 \mu\text{M}$). The high AmB concentration for the direct disruptive action may be attributed to the use of concentrated vacuoles in the assay, otherwise this may be elucidated by reduced interaction between AmB and its molecular target possibly in the vacuole membrane under the hypertonic condition used for the maintenance of vacuole architecture. Filipin III, a polyene macrolide antibiotic, is used as a fluorescent probe to determine the subcellular localization of ergosterol in *S. cerevisiae*.¹⁵ This fluorescent probe could visualize ergosterol in the plasma membrane of intact cells and its mobilization into the cytoplasmic compartment in response to AmB treatment. As in the case with *S. cerevisiae*, the enhancement effect of allicin on AmB lethality as well as vacuole disruption (see Figures 2b and 4e) was accompanied by the inhibition of ergosterol transport from the plasma membrane into the cytoplasm of *C. albicans* cells (see Figure 7d). Taking into consideration that ergosterol treatment prevented the enhancement of AmB lethality by allicin, we propose that allicin enhances the vacuole-targeting fungicidal activity of AmB against this pathogenic fungus by inhibiting a mechanism of intracellular ergosterol transport.
