

THE DISTRIBUTION OF THE RH(D) BLOOD TYPES IN JAPAN¹

Yoshiko FUJITA, Katumi TANAKA, and Masako TANIMURA

Department of Human Genetics, Tokyo Medical and Dental University, Tokyo

Summary Data on the Rh(D) types of 2,745,618 individuals were collected from prefectural health departments, health centers, and Red Cross blood centers in 35 of 47 prefectures in the whole country. Phenotypic and gene frequencies for each subpopulations were calculated and tabulated.

The frequency of Rh(D) negatives in the whole sample is 0.5428% and the frequency of the Rh(D) negative gene is estimated to be $7.37 \pm 0.03\%$. An insignificant cline of the frequencies is suggested, *i.e.* the Rh(D) negative gene is increased from the northeast to the southwest of Japan.

INTRODUCTION

Frequencies of Rh blood types in different localities in Japan were summarized by Akaishi and Kudo (1975) who compiled available data on 10 prefectures from literature and through their own surveys. A majority of the studied prefectures cluster in the northmost part of the country and, therefore, distribution of the Rh system in the whole of Japan was still uncertain.

Recently, examination of the Rh(D) type is extensively carrying out at health centers and blood centers in the whole country. The present authors collected such data and report here the results of the analyses.

MATERIALS AND METHODS

The data on the numbers of Rh(D) positives and negatives were obtained from health centers, prefectural health departments and Red Cross blood centers by mail. Most data from Kagoshima Prefecture became available through Prof. Tetuo Zyo, Kagoshima University. Thus, data on the distribution of Rh(D) negatives were available from 35 of 47 prefectures for 2,745,618 individuals, in total.

The blood-typing was carried out during the period from 1964 to 1975, mostly from 1970 to 1973.

Received March 2, 1978.

¹ This study was supported by the Scientific Research Grant from the Ministry of Education, Science and Culture of Japan No. 037020 in 1975, and No. 137071 in 1976 and 1977.

Frequency of the Rh(D) negative allele was calculated simply by $d = \sqrt{n_d/N}$, where n_d denotes the number of Rh(D) negative individuals and N the size of the sample.

RESULTS

The phenotypic frequency of Rh(D) negative individuals in the entire sample was 0.5428% and frequency of the Rh(D) negative allele was estimated to be $7.37 \pm$

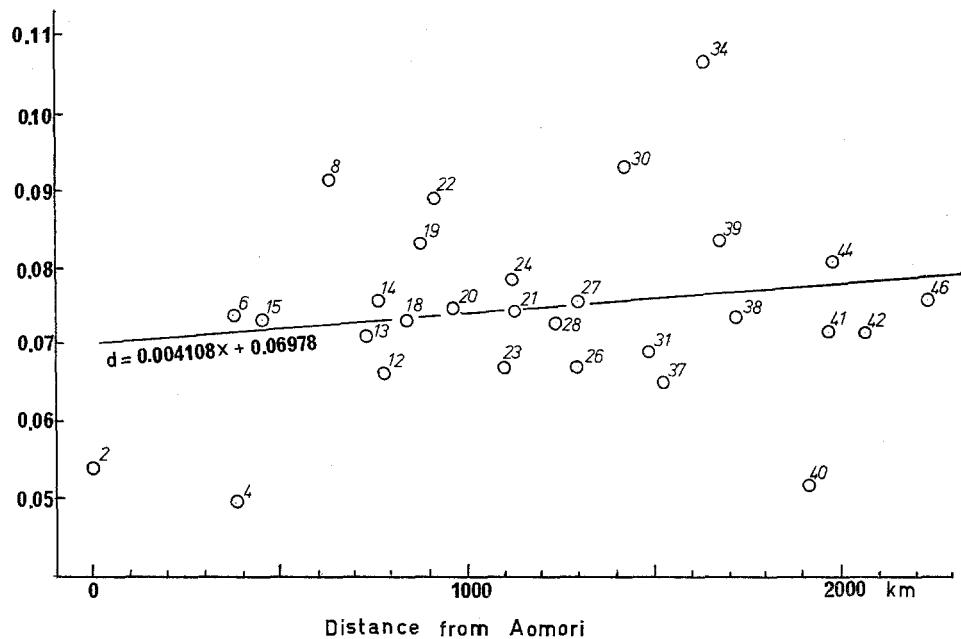

Fig. 1. Gradient of the frequency of the Rh(D) negative allele, d.

0.03%. The frequencies for prefectures are shown in Table 1 and those for health centers and districts in each prefecture are listed in the appendix. Each number of prefecture in italic and health center or district in roman corresponds to that shown in maps (Figs. 1 and 6-14) in a previous paper on the distribution of the ABO system (Fujita *et al.*, 1978).

The frequency of the Rh(D) negative gene for each prefecture and the distance measured from Aomori, the northernmost of the Honshu Island, to each prefecture capital along the National Railroad were plotted in Fig. 1, which suggests a slight increase of the gene frequency with the increasing distance. An analysis of the data on 29 prefectures, excluding 6 prefectures with sample sizes smaller than 1,000, revealed that the correlation coefficient between the distance from Aomori and the frequency of Rh(D) negative gene is 0.193, which deviates from zero insignificantly ($t=1.022$ with 27 degrees of freedom, $0.3 < P < 0.4$). The regression equation of the gene frequency on the distance in 1,000 kilometers, x , is $d=0.004108x+0.06978$.

DISCUSSION

The frequency of the Rh(D) negatives in the whole sample is not greatly different from those reported by previous authors in various populations in Japan, excluding the Ryukyuans and the Ainu (see Akaishi and Kudo, 1975). As shown in Table 1, the frequency of Rh(D) negative gene for prefecture ranges from zero to 10% or higher.

Such a wide variation is mostly attributable to the smallness of the sample sizes. The range in 6 prefectures with samples larger than 100,000 is as narrow as 7.13–7.85%.

On the other hand, it was suggested that the frequency of the Rh(D) negative gene was increased from the northeast to the southwest, though insignificantly. Such a cline may not be unexpected, since the frequencies of the Rh(D) types in the neighboring races are different from those in the Japanese and there are known significant clines of the frequencies of some polymorphic genes, including ABO blood group genes in Japan (Kobayashi, 1940; Tanaka, 1959; Nei and Imaizumi, 1966; Fujita *et al.*, 1978). Frequency of the Rh(D) negative gene in Okinawa is apparently higher than that in other districts of Japan (Nakajima *et al.*, 1967b; Waki, 1972). This may accord with the cline of the gene frequency which increases from the northeast to the southwest.

However, the Rh(D) negative gene is much more frequent in the Ainu (Kobayashi, 1953, 1956; Ishibashi, 1971; Misawa and Hayashida, 1972; Misawa *et al.*, 1975), the original inhabitants in the northmost districts of Japan, and much rarer in Korean (Sarkisian, 1956; Won, 1960; Won *et al.*, 1960; Mourant *et al.*, 1976) and Taiwanese (Nakajima *et al.*, 1967a, 1971) who have had close contacts particularly with the southwest districts of Japan. Thus, it may be premature to deduce a decisive explanation of the relationship between the distributions of Rh(D) negative gene in the Japanese and surrounding races.

Acknowledgment The authors are greatly indebted to health centers, prefectoral health departments and Red Cross blood centers and their staffs, and Prof. T. Zyo, Kagoshima University Medical School, for the cordial cooperation of the collection of the data. They wish to express deepest appreciation to Dr. Hachiro Nakajima, Department of Legal Medicine, Tokyo Medical and Dental University, for valuable advices.
