Acute myeloblastic leukemia (AML) is characterized by the accumulation of abnormal myeloblasts (mainly granulocyte or monocyte precursors) in the bone marrow and blood. Though great progress has been made for improvement in clinical treatment during the past decades, only minority with AML achieve long-term survival. Therefore, further understanding mechanisms of leukemogenesis and exploring novel therapeutic strategies are still crucial for improving disease outcome. MicroRNA-100 (miR-100), a small non-coding RNA molecule, has been reported as a frequent event aberrantly expressed in patients with AML; however, the molecular basis for this phenotype and the statuses of its downstream targets have not yet been elucidated. In the present study, we found that the expression level of miR-100 *in vivo* was related to the stage of the maturation block underlying the subtypes of myeloid leukemia. *In vitro* experiments further demonstrated that miR-100 was required to promote the cell proliferation of promyelocytic blasts and arrest them differentiated to granulocyte/monocyte lineages. Significantly, we identified RBSP3, a phosphatase-like tumor suppressor, as a bona fide target of miR-100 and validated that RBSP3 was involved in cell differentiation and survival in AML. Moreover, we revealed a new pathway that miR-100 regulates G1/S transition and S-phase entry and blocks the terminal differentiation by targeting RBSP3, which partly in turn modulates the cell cycle effectors pRB/E2F1 in AML. These events promoted cell proliferation and blocked granulocyte/monocyte differentiation. Our data highlight an important role of miR-100 in the molecular etiology of AML, and implicate the potential application of miR-100 in cancer therapy.

Introduction

Acute myeloblastic leukemia (AML) arises from the differentiation arrest of myeloid precursor and malignant proliferation in the bone marrow (BM) and blood. It can be divided into different subtypes based on the cell type and the degree of maturity (Lowenberg *et al.*, 1999). Although much progress has been achieved in the clinical treatment of AML in recent decades, only approximately 40% of patients with AML achieve long-term survival (Farag *et al.*, 2005; Estey and Döhner, 2006; Estey, 2007). Therefore, a better understanding of the mechanisms responsible for leukemogenesis and an exploration of novel therapeutic strategies are crucial for achieving an improved outcome.

The differentiation of AML lineages is regulated by a dynamic interaction between lineage-specific regulators, including microRNAs (miRNAs), which have key roles in hematopoiesis (Chen, 2005; Fontana *et al.*, 2007; Jongen-Lavrencic *et al.*, 2008; Han *et al.*, 2010). MiRNAs, a novel class of small non-coding RNAs that range from 19 to 25 nucleotides in length, can silence specific target genes through translational repression or direct mRNA degradation (Bartel, 2004; Lim *et al.*, 2005). The deregulated expression of specific miRNAs that modulate the expression of oncogenes and tumor suppressors is associated with the development of malignancies (Chen, 2005; Esquela-Kerscher and Slack, 2006). Currently, several miRNAs have been reported as oncogenes or tumor suppressors in leukemia (Fazi *et al.*, 2005; Fontana *et al.*, 2007; Bousquet *et al.*, 2008; Garzon *et al.*, 2009; Pigazzi *et al.*, 2009; Han *et al.*, 2010; Liu *et al.*, 2010). A few reports have described miRNA expression that is highly regulated according to the developmental lineage of the cell and restricted miRNA expression profiles during hematopoiesis. For example, miR-125b-1 arrests myeloid cell differentiation in myelodysplastic syndrome (MDS) and in AML

(Bousquet *et al.*, 2008), and miR-223 regulates the differentiation of human granulopoiesis (Fazi *et al.*, 2005). MiR-424 stimulates monocyte differentiation via the translational repression of NFI-A (Rosa *et al.*, 2007), and a restricted miRNA signature distinguishes APL blasts from normal promyelocytes (Careccia *et al.*, 2009). However, the functions of other miRNAs in leukemia have been minimally explored.

MiR-100 is aberrantly expressed in a number of cancer cells, including AML cells with a t(15;17) (Jongen-Lavrencic *et al.*, 2008; Li *et al.*, 2008; Varnholt *et al.*, 2008; Leite *et al.*, 2009). A few studies have also reported that miR-100 regulates the expression of Polo-like kinase 1 in nasopharyngeal cancer, whereas it targets mTOR in adrenocortical cancer cells and in clear cell ovarian cancer (Nagaraja *et al.*, 2010; Shi *et al.*, 2010). These results suggest that miR-100 might function as a tumor suppressor or as an oncogene in different cancers. We have previously found that miR-100 is significantly upregulated in AML patients at the time of diagnosis (Zhang *et al.*, 2009). This finding raises the possibility that miR-100 might have an important role in the development or pathogenesis of AML. However, the molecular basis for this phenotype has not been elucidated, and the status of the downstream targets of miR-100 in AML remains unknown.

In the present study, we explored the functional role of miR-100 in AML. We found that miR-100 was highly expressed in AML, particularly in acute granulocytic leukemia, and the expression levels of miR-100 were related to the stage of the maturation block underlying the myeloid leukemia subtypes. *In vitro* experiments further demonstrated that miR-100 overexpression in AML cells inhibited RBSP3 and in turn led to an increase in the level of phosphorylated pRB and in the release of E2F1. These events promoted cell proliferation and blocked granulocyte/monocyte differentiation. The present results suggest that miR-100 may serve as a novel therapeutic target in AML.

Results

MiR-100 expression is upregulated in primary AML

Using diagnostic BM samples, we analyzed miR-100 expression in 48 patients with AML, 9 with the AML-M1 (according to the FAB classification) subtype, 7 with AML-M2, 18 with AML-M3, 4 with AML-M4 and 10 with AML-M5. Five BM samples from healthy donors were analyzed as controls. The characteristics of the patients were shown in Table 1. Figure 1a showed that miR-100 is expressed at low levels in total nucleated cells from BM of healthy donors. Upregulated miR-100 expression was detected in almost all of the subtypes, and the expression of miR-100 was much higher in AML-M1, M2 and M3 (Figure 1a). More interestingly, miR-100 was detected at the higher levels of expression in the AML-M1 presenting the immature myeloid phenotype, and slightly increased its expression in the myeloblastic AML-M2 subtype and at the highest

Table 1 AML patients' characteristics

Characteristics	Median (range)	No. (%)
Sex

levels of expression in primary AML-M3. These results showed that miR-100 exhibited high expression in myeloid cells that commit to differentiate to granulocyte and monocyte cells in normal program while differentiation arrest in AML, strongly implying the relationship of upregulation of miR-100 and myeloid cell's differentiation block.

We have also detected the expression of miR-100 precursor in the clinical samples (Figure 1b) and found that miR-100 precursor is extremely higher in AML-M1, M2 and M3, consistent with mature miR-100 expression. These results suggest that aberration of miR-100 expression was not at the processing level.

Upregulation of miR-100 arrests human granulocyte and monocyte differentiation and promotes cell survival

To investigate the potential role of miR-100 in myeloid cell differentiation, especially in promyeloid stages, we first examined the expression profiles of miR-100 during the differentiation of the myeloid leukemia cell line HL60 during induction with all-trans retinoic acid (ATRA) and 1,25-dihydroxy-vitamin D₃ (1,25D₃), which can inhibit cell growth and induce granulocyte and monocyte phenotypes, respectively (Supplementary Figures S1 and S2) (Collins *et al.*, 1990; Ji and Studzinski, 2004). The expression of miR-100 was detected at 48 h and 96 h after the treatments. The miR-100 expression level decreased in response to both drugs in a dose-dependent (Figures 1c and d) and time-dependent manner (Figures 1e and f). Moreover, miR-100 precursor expression was determined after 12 h and 96 h of ATRA and 1,25D₃ treatment by northern blot (Figure 1g). A reduced expression level of miR-100

Figure 1 Expression of miR-100 in AML patients and the human leukemia cell line HL60 following induction with all-trans retinoic acid (ATRA) and 1 α , 25-dihydroxyvitamin D₃ (1,25D₃). (a, b) The expression level of mature miR-100 (a) and miR-100 precursor (b) in AML patients (from AML M1 to M5), respectively, was quantified by real-time PCR, normalized to the expression of U6 and presented as the $2^{-\Delta\Delta Ct}$ value relative to the normal samples. Both mature miR-100 and miR-100 precursor was significantly upregulated in the M1, M2 and M3 subtypes in comparison with the healthy controls, but a low expression level was detected in the M4, M5 subtypes (** $P < 0.01$). (c, d) MiR-100 expression was detected in HL60 cells after 48 h and 96 h of treatment with different concentrations of ATRA (c) and 1,25D₃ (d) by qRT-PCR, respectively. (e, f) A time-dependent downregulation of miR-100 in HL60 cells was observed following exposure to 1 μ M ATRA (e) and 100 nM 1,25D₃ (f). The asterisks demonstrate statistically significant differences compared with the corresponding vehicle-treated control (CTL) (* $P < 0.05$). (g) MiR-100 precursor expression was determined at 12 h and 96 h after treatment of 1 μ M ATRA or 100 nM 1,25D₃, respectively, by Northern blot. The value under each sample indicates the fold change of miR-100 precursor level in ATRA- or 1,25D₃-treated cells, relative to that in CTL. A full colour version of this figure is available at the *Oncogene* journal online.

precursor is similar to that of same as mature miR-100 during both granulocytic and monocytic differentiation, which suggested that miR-100 negatively regulated promyeloid cell terminal differentiation.

Next, we examined whether the overexpression of miR-100 could arrest cell differentiation. HL60 cells were transfected with the negative control RNA duplex (denoted miR-NC) or miR-100 mimics, and then treated with either ATRA or 1,25D₃. The miR-NC has been

demonstrated to have minimal sequence identity with human miRNA (Dharmacon, Lafayette, CO, USA). Transfection efficiency of miR-100 mimics was determined by qRT-PCR (Supplementary Figure S3A).

As shown in Figures 2a and b, the expression levels of both CD11b and CD15 increased following ATRA treatment. Notably, miR-100-transfected cells clearly displayed low expression levels of the differentiation markers in comparison with miR-NC-transfected cells

Figure 2 Role of miR-100 in granulocytic/monocytic differentiation and myeloid cell proliferation. (a–d) Transient transfection of HL60 cells with miR-100 blocked the granulocytic differentiation induced by ATRA. Percentage of CD11b and CD15 positive cells in HL60 cells 72 h after electroporation with H₂O or the miRNA duplex as follows: (a) H₂O without ATRA, (b) H₂O with ATRA, (c, d) miR NC or miR-100 mimics with ATRA. (e–h) Experiments corresponding to a–d but with 1,25D₃ treatment and percentage of CD11b and CD14-positive cells were determined. (i–m) Morphological analysis of HL60 cells at day 4 after electroporation with H₂O or the miRNA duplex as follows: (i) H₂O without ATRA, (j) H₂O with ATRA, (k) miR-NC with ATRA and (l) miR-100 duplex with ATRA. A representative experiment is shown. (m) Graphic representation of the morphological data corresponding to the mean of three independent experiments. The number of differentiated granulocytic cells compared with the number of undifferentiated cells (without ATRA). (n–r) Experiments corresponding to i–m but with 1,25D₃ treatment. (s, t) MiR-100 significantly promotes cell proliferation in HL60 (s) and NB4 (t) cells used CCK-8 assay kit. All of the values in the histograms represent the means ± s.e.m. of triplicate determinations.

(Figures 2a–d). In particular, the expression of CD15 was reduced significantly. A maturation arrest of monocytic differentiation was also observed. As shown in Figures 2g and h, the markers of monocytic differentiation CD11b and CD14 were reduced in miR-100-transfected HL60 cells in response to treatment with 1,25D₃ (Figures 2e–h). The differentiation toward granulocytic/monocytic lineages was further confirmed based on morphology (Figures 2i–r). These results indicated that miR-100 overexpression could significantly prevent differentiation toward both lineages.

In addition, we assessed whether miR-100 had an effect on cell proliferation using the CCK-8 assay. As expected, the proliferation of HL60 cells was stimulated by the overexpression of miR-100 (Figure 2s, $P < 0.05$ at 48 h and $P < 0.01$ from 72 h to 96 h), and this effect was time-dependent. However, no clear dose-dependent effect was detected. Similar results were observed in NB4 cells (Figure 2t, $P < 0.01$). These data suggested that miR-100 might function as an oncogene and contribute to AML progression by blocking myeloid cell differentiation and promoting proliferation.

MiR-100 targets the phosphatase-like gene RBSP3 via translational repression

The elucidation of miRNA targets remains a major issue in functional investigations of miRNAs. Putative targets of miR-100 were searched using TargetScan (<http://www.targetscan.org/>), PICTAR (<http://pictar.bio.nyu.edu/>) and miRBase (<http://microrna.sanger.ac.uk/sequences/index.shtml>) and 37 potential targets were predicted. Among the predicted targets, 10 are related to tumorigenesis and thus were selected for further experimental validation (Supplementary Table S1 and part data shown in Supplementary Figure S3). Three putative targets were experimentally confirmed, including RB1 serine phosphates from human chromosome 3 (*RBSP3*), tribbles homolog 2 (*TRIB2*) and homeobox A1 (*HOXA1*). Remarkably, *RBSP3* demonstrated the greatest reduction of activity (40%). The predicted miR-100-binding 3' UTR of *RBSP3* is conserved in humans, mice and rats (Figure 3a), and the interaction between miR-100 and target mRNA sequences was further validated using luciferase reporter assays with a deleted, point and full mutation of putative miR-100 binding sites in the 3' UTR of the *RBSP3* gene (Figures 3b and c).

To confirm that the RBSP3 protein is suppressed by miR-100, we performed both miR-100 overexpression and knockdown experiments in HL60 cells and examined the expression of RBSP3. As shown in Figure 3d, the level of RBSP3 protein was significantly reduced in HL60 cells that were transfected with the miR-100 mimic, but it was increased in cells that were transfected with the miR-100 inhibitor (antisense), which transfection efficiency was determined by qRT-PCR (Supplementary Figure S3B). These data indicated that RBSP3 is a bona fide target of miR-100 in myelopoiesis.

To further validate the correlation of miR-100 and RBSP3 *in vivo*, we have chosen 17 cases at random to

determine the expression of miR-100 and the protein levels of RBSP3 in primary patients. Figure 3e showed that the expression of RBSP3 is extremely low in AML-M3, and reversely correlated with miR-100 in AML about 76.5%.

The RBSP3 gene is involved in myeloid cell differentiation and cell proliferation via the dephosphorylation of RB and the release of E2F1

RBSP3, which has been previously denoted as *HYA22* and *CTDSPL*, is a recently identified phosphatase-like tumor suppressor gene that dephosphorylates the Rb1 serine on Ser-807 and Ser-811 (Kashuba *et al.*, 2004). A recent study revealed that RBSP3 is involved in the regulation of cell growth and differentiation, and frequent mutations in this gene are detected in human hematopoietic cell lines (Kashuba *et al.*, 2009). However, the function of RBSP3 in leukemia has not yet been elucidated.

To explore whether RBSP3 is involved in myeloid cell differentiation, we first determined the expression level of RBSP3 protein in HL60 cells following induction with ATRA or 1,25D₃. A significant increase in RBSP3 protein levels was detected in response to both treatments (Figures 3f and g). Notably, the expression level of RBSP3 increased in a dose- and time-dependent manner (Figure 3h), and this phenomenon correlated negatively with miR-100 expression (Figures 1c–f). The results further demonstrated that RBSP3 reversed the effects of miR-100 and had a role in promyeloid cell differentiation.

To further unravel the function of RBSP3, loss- and gain-function were performed with RNA interference and lentivirus construct, respectively, to confirm the role of this gene in cell differentiation and proliferation. Among two siRNAs duplexes (siRBSP3-1 or 2), siRBSP3-2 caused an obvious reduction in both endogenous mRNA and protein levels in HL60 cells, which was selected for further study (Figure 4a). Meanwhile, RBSP3 protein level was increased in HL60 cells infected by lentivirus-RBSP3 (lv-RBSP3) compared with lentivirus negative control (lv-NC) (Figure 4b). As expected, reduced CD11b and CD15 expression levels were detected in siRBSP3-2-transfected HL60 cells, while increased CD11b and CD15 expression in lentivirus infected ones in comparison with the controls following treatment with ATRA (Figures 4c–h). Similarly, CD11b/CD14 inhibition and elevation was observed in siRBSP3 and lentivirus transduced cells, respectively, following 1,25D₃ treatment (Figures 4i–n). These results suggest that RBSP3 promotes promyeloid cell differentiation. We further explored the role of RBSP3 in cell proliferation using the CCK-8 assay. HL60 cells survival gradually increased from 24 h to 96 h following transfection with siRBSP3 (Figure 4o), while suppressed in cells with lentivirus infected (Figure 4p). These results were similar to that obtained in the miR-100 studies, which indicates that RBSP3 functions as a suppressor of cell growth in AML.

Previous studies have shown that RBSP3 can influence the phosphorylation status of pRB and then

Figure 3 MiR-100 directly targets RBSP3, which responds to ATRA and 1,25D₃ induction. (a) Sequences of the predicted miR-100 binding sites in human, mouse and rat genomic regions. Highly conserved nucleotides are shown in blue. (b) Schematic of the luciferase reporter assay used to validate the interaction between miR-100 and the 3' UTR of *RBSP3*. Red font indicates the 'seed' regions. MRE *RBSP3* 3' UTR of wild, deleted, point mutant and full mutant were separately inserted into a psiCheck2 vector downstream from the Renilla luciferase gene. (c) Repression of luciferase activity due to the interaction between miR-100 and the luciferase constructs. Each Renilla luciferase reading was normalized to that obtained for the control firefly luciferase. (d) Western blot analysis of the expression level of RBSP3 following the overexpression of miR-100 mimics or the knockdown of endogenous miR-100 using miR-100 antisense in HL60 cells. (e) Inverse correlation of expression levels of miR-100 and RBSP3 protein in AML patients (from AML-M1 to M5) demonstrated by qRT-PCR and western blot. (f, g) Time-course analysis of the induced upregulation of RBSP3 protein in HL60 cells by 1 μ M ATRA and 100 nM 1,25D₃, respectively. RBSP3 protein was gradually upregulated from 4 h to 24 h after treatment with 100 nM 1,25D₃. (h) Dose-dependent effect of ATRA and 1,25D₃ on RBSP3 protein expression at 96 h after treatments. RBSP3 protein expression increased in a dose-dependent manner following treatment with 0.1 μ M/1 μ M ATRA or 1 nM/100 nM 1,25D₃. A full colour version of this figure is available at the *Oncogene* journal online.

the release of E2F1. Next, we asked whether RBSP3 has functional relevance with the reduction of the phosphorylated form of pRB protein and blockage of E2F1 in myeloid cells. To address this issue, we transfected siRBSP3 into HL60 cells and found that the expression levels of pRB and E2F1 protein increased with the downregulation of RBSP3, while the amount of total RB protein remained approximately the same in all of the treatments (Figure 5a). These data implied that

RBSP3 might have a crucial role in myeloid cell differentiation toward granulocytic/monocytic lineages through the pRB-E2F1 pathway.

MiR-100 regulates cell differentiation and survival via its target RBSP3, which in turn modulates the cell cycle effector pRB/E2F1 in myeloid cells

As we demonstrated that miR-100 could block differentiation and promote proliferation in AML cells by

repressing the expression of RBSP3, a bona fide target of miR-100, and RBSP3 has a crucial role in cellular differentiation and proliferation in the myeloid lineage through pRB-E2F1, we hypothesized that miR-100

might contribute to the pathogenesis of AML via the RBSP3-pRB-E2F1 pathway.

We tested these hypotheses by transfecting miR-100 mimics and the miR-100 inhibitor into HL60 cells. The

Figure 5 MiR-100 targets RBSP3, which modulates the cell cycle effectors pRB/E2F1 and is involved in myeloid cell differentiation and proliferation. (a) RBSP3 knockdown promoted the phosphorylation of Rb and E2F1. After 72 h transfection with siRNA NC or siRBSP3, cells were collected to analyze the expression of RBSP3, pRb (phosphorylated Rb), Rb (total Rb protein) and E2F1 by western blotting using β -actin as an internal control. (b) MiR-100 overexpression induced the expression of pRb and E2F1 by downregulating RBSP3. The cells were collected at the indicated time points for western blot analysis. (c) The knockdown of miR-100 expression results in an upregulation of RBSP3 expression and a downregulation of pRb and E2F1 expression. Cells were collected at the indicated time points after transfection with miRNA antisense. Protein expression was assessed by western blot analysis. pRb, phosphorylated Rb; Rb, total Rb protein; β -actin, internal control. (d–g) MiR-100 promoted entry into S-phase of the cell cycle. (d) The cell cycle phase was analyzed by FACS at 24 h after the transfection with H₂O in HL60 cells (without nocodazole). (e–g) Cell cycle phase data in HL60 cells transfected with H₂O, miR-NC or miR-100 (with nocodazole). The data correspond to the mean of three independent experiments ($P < 0.05$). (h) Schematic representation of a pathway modulated by miR-100 in myeloid cells undergoing differentiation toward granulocytosis/monocytosis and proliferation in AML. MiR-100 overexpression in myeloid cells induced progression through the G1/S transition and promoted S-phase entry. Thus, miR-100 induced cell proliferation and blocked promyeloid differentiation by repressing its downstream target RBSP3, which in turn resulted in the phosphorylation of RB and an accumulation of the downstream cell cycle effector E2F1.

Figure 4 RBSP3 is involved in myeloid cell differentiation and cell proliferation. (a) The qRT-PCR and western blot analysis of the effects of different items of siRBSP3. $*P < 0.05$. (b) Western blot analysis of the infection efficiency of Lentivirus RBSP3. (c–h) CD11b/CD15 expression following transfection with H₂O, siRBSP3 or lv-RBSP3 by FACS ($P < 0.05$); (e, f) H₂O without or with ATRA, (e, f) miR NC or miR-100 with ATRA and (g, h) lv-NC and lv-RBSP3 with ATRA. A representative experiment is shown. (i–n) Corresponding FACS experiments with c–h but the cells were treated with 1,25D3. A representative experiment is shown. (o) The transfection of HL60 cells with siRBSP3 significantly promoted myeloid cell proliferation. Cell viability was determined using the CCK-8 assay. The time points after transfection with H₂O, siRNA NC, siRBSP3, miR-NC or miR-100 are indicated. (p) Corresponding FACS experiments with (o) but the cells were transfected with H₂O, anti-miR-NC, anti-miR-100, lv-NC or lv-RBSP3. $*P < 0.05$. A full colour version of this figure is available at the *Oncogene* journal online.

overexpression of miR-100 resulted in the downregulation of RBSP3 protein at different time points. However, the expression levels of the pRB and E2F1 proteins increased, and the total levels of RB protein remained the same at all time points (Figure 5b). Meanwhile, the results for the protein expression levels of RBSP3, pRB and E2F1 in anti-miR-100 transfectants were opposite with those obtained for miR-100, excluding the findings determined for RB, which remained unchanged in any case (Figure 5c). These results support the hypothesis that miR-100 regulates the RBSP3–pRB–E2F1 pathway at the level of translation.

Because the downstream target E2F1 is a master cell cycle regulator, we also analyzed the cell cycle by FACS to identify S activation via the overexpression of miR-100. The transfected cells were synchronized by treatment with nocodazole, which depolymerizes the microtubules and blocks the cell cycle at G2/M-phase. After 24 h of synchronization, cells were determined by FACS analysis. Results showed that a substantial increase in the G2 population was observed, while most of the miR-100-transfectants could escape this block and enter S-phase (Figures 5d–g). These results further support the hypothesis that miR-100 activates the downstream effector E2F1 and promotes S-phase entry.

Collectively, these results demonstrate that miR-100 contributes to AML pathogenesis by targeting the RBSP3–pRB–E2F1 pathway to affect cell proliferation and differentiation.

Discussion

The inhibition of hematopoietic precursor differentiation is a characteristic of different types of AML. Several studies have shown that genome-wide gene expression patterns are highly related to different subtypes of AML, and have provided a better understanding of the underlying biology of this disease. Recently, miRNAs have emerged as important cellular regulators that mediate cellular development and differentiation. Previous studies have shown that miR-100 is aberrantly expressed in several types of leukemia, including AML with t(15;17) or inv(16) (Dixon-McIver *et al.*, 2008; Li *et al.*, 2008). In the present study, we found that miR-100 inhibits differentiation of myeloid cells toward granulocyte/monocyte lineages. The underlying molecular pathway responsible for the effects of miR-100 in myeloid leukemia cell survival and differentiation might control the G1 to S phase transition by repressing RBSP3, which modulates the RB-E2F1 signaling pathway. We propose that a high expression level of miR-100 may disrupt the cell cycle control, promote cell proliferation, block cell differentiation and consequently facilitate the development of cancers such as AML. These effects characterize a new role for miR-100.

Two observations confirm our hypothesis. First, we observed a differential expression pattern of miR-100 in different subtypes of AML, and interestingly, we found that miR-100 precursor and mature were highly

expressed in AML-M1, M2 and M3. In contrast, lower expression levels were noted in other AML subtypes, such as the M4 and M5 phenotypes, in which the cellular programs for monocytic phenotype are already partially established. Actually, our results indicated that miR-100 could block myeloid cell differentiation and promote cell proliferation during both granulocytic and monocytic differentiation. Next, we investigated the molecular pathway that might be controlled by miR-100. Several putative targets were predicted and notably, RBSP3 was validated. Importantly, expression of RBSP3 protein is most inverse correlation with miR-100 in AML clinical samples. *RBSP3* is an important candidate tumor suppressor gene located at 3p21.3 (Kashuba *et al.*, 2004; Anedchenko *et al.*, 2008; Sinha *et al.*, 2008; Ghosh *et al.*, 2010; Senchenko *et al.*, 2010); however, the involvement of RBSP3 in the regulation of cell differentiation and growth in myeloid cells has not yet been studied. We demonstrated that RBSP3 protein expression was elevated during ATRA- and 1,25D₃-induced promyeloid cell differentiation toward granulocytic and monocytic lineages, respectively. Moreover, loss- and gain-function were introduced to demonstrate that RBSP3 is associated with cell differentiation and proliferation with RNA interference and lentivirus constructs. Expression profiles of CD11b/CD15 or CD11b/CD14 have been detected either downregulated or upregulated in knockdown or overexpressed-RBSP3 cells, respectively, which were similar to the results obtained in ectopic miR-100 expression. These results indicate that the activation of the phosphatase RBSP3 protein may be a common step that is required for granulocytic/monocytic differentiation.

Previous studies have also reported that RBSP3 removes the phosphate group from serine 807 and 811 in its substrate, phosphorylated RB (pRB), and thereby, it induces the formation of the RB-E2F1 complex (Ghosh *et al.*, 2010). The ‘RB’ pathway has a critical role in both cell physiology and tumorigenic transformation via distinct molecular mechanisms, in particular, through the mediation of G1 progression and the G1/S transition (Chen *et al.*, 1989; Strauss *et al.*, 1995; Weinberg, 1995; Bartek *et al.*, 1996, 1997; Hall and Peters, 1996; Sherr, 1996). In the present study, overexpression experiments showed that enforced expression of miR-100 could inhibit RBSP3, upregulate pRB and release E2F1. The release of E2F1 blocks the differentiation induced by ATRA or 1,25D₃ and promotes the survival of HL60 cells. The knockdown experiment revealed that the loss of miR-100 provided the opposite result. These findings indicate that the aberrant expression of pRB-E2F1 and RBSP3 during differentiation and proliferation might be correlated with the expression level of miR-100. In AML cells, a high expression level of miR-100 represses the expression of RBSP3, which in turn leads to increased pRB phosphorylation and E2F1 release. The release of E2F1 might provide a G1/S transition checkpoint and activate progression through S-phase, thus arresting promyeloid cell differentiation, inducing proliferation and leading to AML progression. The schematic representation of the role of

miR-100/RBSP3/pRB/E2F1 in granulocyte/monocyte differentiation and proliferation in AML is shown in Figure 5h.

To date, an increasing number of studies have revealed that miRNAs have an important role in AML. For example, Garzon *et al.* (2009) found that miR-29b has a tumor suppressor function and affects the survival of AML cells by targeting MCL-1 and upregulating BIM and PDCD4 transcripts. Liu *et al.* (2010) discovered the Sp1/NFkB/HDAC/miR-29b regulatory network in KIT-driven AML. Pigazzi *et al.* (2009) demonstrated that miR-34b targets the cyclic AMP-responsive element-binding network in AML. Recently, Pulikkan *et al.* (2010) reported that E2F1 and miR-223 comprise an autoregulatory negative feedback loop in AML. E2F1 is a cell cycle regulator, inhibits granulopoiesis and induces myeloid cell cycle progression (Strom *et al.*, 1998). E2F1 is regulated directly by miR-330 in prostate cancer cells (Lee *et al.*, 2009), by miR-149* in neuroblastoma cells and HeLa cells (Lin *et al.*, 2010) and by miRNA-331-3p in gastric cancer cells (Guo *et al.*, 2010). In addition, 1,25D₃ induces monocytic phenotype differentiation in HL-60 human myeloid leukemia cells, and this process is mediated by Akt through Raf/MEK/ERK MAPK signaling (Wang *et al.*, 2009). To our knowledge, this is the first report to clearly demonstrate the mechanism by which miR-100 inhibits RBSP3 during granulopoiesis and monocytic differentiation. MiR-100 targets RBSP3 and regulates its expression in AML, which reveals a new post-transcriptional mechanism of regulation in the myeloid lineage. In addition, another kinase mTOR was also validated as a target of miR-100 in AML in this study, suggesting that miR-100 may involve in a complicated network. The manipulation of miR-100 could be diagnostically and therapeutically relevant to treat AML subtypes.

Materials and methods

Patients, sample collection and therapeutic methods

A total of 48 AML patients and five healthy donors from the First and Second Affiliated Hospital of Sun Yat-sen University were enrolled in the study. The demographics for all of the patients are presented (see Table 1). The BM from patients and healthy donors was collected via a BM puncture at the time of diagnosis or during the follow-up process. Written informed consent to perform the biological studies was obtained from all of the patients, and the study was approved by the Ethics Committee of the affiliated hospitals at Sun Yat-sen University.

RNA analysis

Total RNA was extracted using Trizol reagent (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's instructions. The following oligonucleotides were used as probes for mature miR-100: RT primer, 5'-GTCGTATCCAGTGCAGGGTCCGAGGTATTCGCACTGGATACGACCACAAG-3'; PCR forward primer, 5'-GCGGC AACCCGTAGATCCGAA-3'; PCR reverse primer, 5'-GTGCAGGGTCCGAGGT-3'. Endogenous U6 small nuclear RNA was detected as an internal control using the following oligonucleotides: forward primer,

5'-CGCTTCGGCAGCACATATAC-3'; reverse primer, 5'-TT CACGAATTTGCGTGTTCAT-3'. MiR-100 precursor primers were designed as describe previously (Jiang *et al.*, 2005). PCR forward primer: 5'-AACCCGTAGATCCGAAGTTG-3'; PCR reverse primer: 5'-TACCTATAGATACAAGCTTGTGCG-3'. U6 small nuclear RNA forwards primer: 5'-CTCGCTTCGG CAGCACA-3'; reversed primer: 5'-AACGCTTCACGAATT TCGGT-3'. The miR-100 precursor and U6 reverse transcription primers were used as the reverse primer. Where indicated, both miRNA mature and precursor quantification was performed by real-time PCR with an ABI PRISM 7900 Sequence Detection System (Applied Biosystems, Foster City, CA, USA). The delta Ct values were normalized to those obtained from the amplification of endogenous U6 small nuclear RNA. All of the reactions were performed in triplicate. Real-time PCR was performed to quantify the mRNA expression using ExTaq SYBR Green Supermix (Bio-Rad, Hercules, CA, USA) according to the manufacturer's instructions. The following oligonucleotides were used for *RBSP3*: forward primer, 5'-CGCTTCGGCAGCACATATAC-3', reverse primer 5'-TTCACGAATTTGCGTGTTCAT-3'. The *RBSP3* transcript was detected using the TaqMan oligonucleotides HS 00325656.m1 (Applied Biosystems). The delta Ct values were normalized to those obtained from the amplification of endogenous β -actin mRNA using the Quantitect Primer Assay (Qiagen, Guangzhou, China). All of the reactions were performed in triplicate.

Northern blot

HL60 cells were treated with 1 μ M ATRA and 100 nM 1,25D₃ at 12 h and 96 h, respectively. Total RNA was extracted with Trizol reagent (Invitrogen) according to the manufacturer's instructions. In all, 80 μ g of total RNA was separated on a 15% denaturing polyacrylamide gel, transferred to positively charged membrane (PerkinElmer, Boston, MA, USA) using Trans-Blot semi-dry electrophoretic transfer cell (Bio-Rad) and then immobilized by UV crosslinking at 354 nm for 4 min each face and baking at 80 °C under vacuum for 50 min. The membranes were pre-hybridized and then hybridized at 42 °C for 24 h to a γ -³²P-labeled DNA oligonucleotide that was complementary to the sequence of miR-100 precursor (probe sequence: 5'-CTTGTGCGGACTAATACCACAAGT TCGGATCTACGGGT-3' and U6: 5'-CCATGCTAATCT TCTCTGTATC-3') thereafter, the membranes were washed and exposed to a Storage Phosphor Screen, which was subsequently read with STORM 820 Phosphor Imager (Amersham Bioscience, Sunyvale, CA, USA).

Vector constructs

The 3'-untranslated terminal region (UTR) segment comprising 59 bp of the 3' UTR of *RBSP3* was synthesized by Sangon (Shanghai, China) and inserted into the psiCheck-control vector (Promega, Madison, WI, USA) for the miRNA functional analysis. The *RBSP3* deleted/psiCheck-*RBSP3*-deleted vector, which spanned 8 bp of the site of perfect complementarity to miR-*RBSP3*, was generated by PCR deletion. The *RBSP3* point mutated/psiCheck-*RBSP3*-point mutated vector was mutated at 1, 3, 4, 6 and 8 point, and the *RBSP3* full mutated/psiCheck-*RBSP3*-full mutated vector was full mutation of the perfect complementarity site, respectively. Wild type, deleted insertions, point mutation and full mutation were confirmed by DNA sequencing.

Statistical analysis

The Fisher's exact test, *t*-test and χ^2 -test were used to compare baseline characteristics and the average miRNA expression

levels between groups of patients and between patients and normal donors. Other data are expressed as the mean $\pm$ s.e.m. of at least three independent experiments. The differences between groups were analyzed using the Student's *t*-test when only two groups were compared or one-way analysis of variance when more than two groups were compared. $P < 0.05$ was considered statistically significant.

Cell lines and transient transfection

Two human acute myeloid leukemic cell lines, HL60 and NB4, were cultured in RPMI 1640 medium (Invitrogen). The human embryonic kidney cell line HEK-293T was grown in Dulbecco's modified Eagle's medium (Invitrogen). Both cultures were supplemented with 10% fetal bovine serum (fetal bovine serum, Australia) and sodium pyruvate and cultured at 37°C in a humidified atmosphere consisting of 5% CO₂.

For the luciferase reporter assay, HEK-293T cells were grown in 24-well plates at a density of 1×10^5 cells per well in 0.5 ml of complete growth medium. The cells were transfected using Lipofectamine 2000 (Invitrogen) according to the manufacturer's protocol.

The following were purchased from GenePharma (Shanghai, China): miR-100 mimics; miR-NC, a miRNA negative control; miR-100 antisense with a sequence complementary to mature miR-100; and miR antisense NC, a negative control for miR-100 antisense. The small interfering RNAs (siRNA) against human *RBSP3* (GenBank Access. No. NM_005808) transcripts (denoted siRBSP3) and the negative control RNA duplex (denoted siRNA NC) were purchased from Guangzhou Ribo-Bio Co., Ltd. (Guangzhou, China).

HL60 and NB4 cells were grown in 24-well plates containing a density of 1×10^6 cells per well in 0.5 ml of complete growth medium. The cells were transfected with the small molecular RNAs mentioned above using the Neon Transfection System (Invitrogen). The electroporation conditions were as follows: 1350 V, 35 ms width and one pulse for HL60 cells; 1400 V, 10 ms width and three pulses for NB4 cells.

Luciferase reporter assay

Transient transfections were performed in HEK-293T cells with 100 nm miR-100 mimics or miR-100 negative control; 0.1 μ g of psiCheck control or psiCheck-RBSP3; or psiCheck-RBSP3-deleted, or psiCHECK-RBSP3-point mutated vector or psiCHECK-RBSP3-full mutated vector containing the firefly luciferase reporter vector and 0.1 μ g of the control vector containing Renilla luciferase (pRL-TK) (Promega). HL60 cells were transfected by electroporation with 100 nm miR-100 negative control, 2.5 μ g of the psiCheck-control or psiCheck-RBSP3 or psiCheck-RBSP3-deleted or psiCheck-RBSP3-point mutated vector, or psiCheck-RBSP3-full mutated vector containing firefly luciferase report vector and 2.5 μ g of the control vector containing Renilla luciferase, pRL-TK (Promega). Firefly and Renilla luciferase activities were measured consecutively at 24 h after transfection using Dual-luciferase assays (Promega) according to the manufacturer's instructions.

Cell proliferation assays

Cell proliferation was determined using the Cell Counting Kit-8 (CCK-8) as described previously (Hamamoto *et al.*, 2004). Cells in a 24-well plate were transfected by electroporation with 100 nm miR-100 mimics, 200 nm miR-100 antisense, 100 nm siRBSP3 and the corresponding doses of miR NC, miR antisense NC and siRNA NC, respectively. After transfection, 1×10^4 cells per well were plated in 96-well plates, and the CCK-8 assay (Dojindo Molecular Technologies, Shanghai, China) was conducted after 24 h, 48 h, 72 h and 96 h.

Evaluation of myeloid differentiation

Lentivirus RBSP3-infected cells and various cells transfected with 100 nm miR-100, 100 nm siRBSP3 and their negative controls by electroporation after 24 h, were treated with 1 μ M ATRA (Sigma-Aldrich, Shanghai, China) and 10 nm 1,25-dihydroxy-vitamin D3 (1,25D₃) (Sigma-Aldrich), respectively. Both granulocytic and monocytic differentiation was evaluated at day 4 after ATRA or 1,25D₃ induction based on the cell morphology on Wright-Giemsa-stained slides. In all, 300 cells were counted to evaluate morphology. The expression of CD11b and CD15 for granulocytic differentiation and the expression of CD11b and CD14 for monocytic differentiation were detected on day 3 after induction by fluorescence activated cell sorter (FACS) analysis. For the FACS assay, the cells were stained with the following anti-human monoclonal antibodies: CD14-PE (eBioscience, San Diego, CA, USA), CD15-perCP (eBioscience), CD11b-APC (Invitrogen), which were measured using a FACSCaliber (BD Bioscience, San Jose, CA, USA). The data were analyzed using FACSDiva software (BD Biosciences). A minimum of 10 000 events were collected for each sample.

Western blot assay

The cells were treated as indicated in the figures and lysed in RIPA buffer (Pierce, Rockford, IL, USA) with protease and phosphatase inhibitors (Roche, Beijing, China). The protein was separated in a 10% polyacrylamide gel and transferred to a methanol-activated PVDF membrane (Millipore, Beijing, China). The membrane was blocked for 2 h in Tris-buffered saline Tween-20 (TBST) containing 2% bovine serum albumin and then probed with polyclonal rabbit anti-RBSP3 (Novus Biologicals, Littleton, CO, USA), anti-phospho-Rb (Ser 807/811) (Cell Signaling Technology, Boston, MA, USA), monoclonal mouse anti-Rb (4H1) (Cell Signaling Technology), anti-E2F1 (clones KH20 and KH95, Upstate Millipore, Guangzhou, China) and polyclonal rabbit anti-glyceraldehyde-3-phosphate dehydrogenase antibodies (Proteintech Technology, Manchester, UK) or anti- β -actin antibody (Cell Signaling Technology) overnight at 4°C. After a 1 h incubation with anti-mouse (Pierce) or anti-rabbit (Sigma-Aldrich) HRP-conjugated secondary antibody, the protein level was detected using a luminal reagent (Millipore).

Cell cycle assay

The cells were transfected with H₂O (denoted as mock), miR NC or miR-100 mimics by electroporation and plated in a 24-well plate. Nocodazole (100 ng/ml) was added to the cells 24 h after transfection. The cells were cultured for an additional 24 h, collected and incubated with NP40/propidium iodide (PI) buffer and 0.5 μ L of RNase (30 mg/ml) for 30 min at 37°C before FACS analysis. PI-negative living cells were gated for the cell cycle analysis.

Lentiviral construction and infection

To overexpress RBSP3 in cells, lentiviral vector was constructed from. Briefly, full-length complementary DNA of *RBSP3* (831 bp) were inserted to pLVX-PGK-IRES-ZsGreen lentiviral control vectors. pLVX-PGK-hRBSP3-IRES-ZsGreen or pLVX-PGK-IRES-ZsGreen and three packaged plasmids co-transfected into HEK-293T cells. Supernatant were harvested at 24 and 48 h after transfection passed through 0.45 μ m and concentrated. In all, 25 μ L lentivirus-RBSP3 (lv-RBSP3) and 5 μ L lentivirus negative control (lv-NC) containing medium was mixed with equal volume 8 μ g/ml polybrene (hexadimethrine bromide, Sigma, St Louis, MO, USA), and then used to infect HL60 cells. After 24 h, target cells were washed twice with PBS and cultured in fresh medium until further analysis.

Conflict of interest

The authors declare no conflict of interest.

Acknowledgements

We thank the following investigators and hospitals that provided samples for the analysis: Dr Hai-Xia Guo at the Second Affiliated Hospital of Sun Yat-sen University; Li-Bing Huang at the First Affiliated Hospital of Sun Yat-sen University; This work was supported by National Science and Technology Department (2011CBA01105, 2011CB811301 and 2009ZX09103-641) and the funds from National Natural

Science Foundation of China (No 30872784 and 81070440), as well as supported by 'the Fundamental Research Funds for the Central Universities'. We thank Nature Publishing Group Language Editing, LLC for editing the text of the manuscript.

Author contribution: YSZ and HZ contributed equally to this work, performing experiments, analyzing the data, and writing the manuscript; XJZ, DDF CWZ and KYL performed and analyzed western blot and qRT-PCR data; XQL and XL provided patient samples and clinical data and designed the experiments; HZ, LHQ and PZ analyzed the data and edited the manuscript; YQC designed experiments and edited the manuscript. All authors critically reviewed the manuscript.
