## NEPHROLOGY

1045 CHANGES IN GLOMERULAR BASEMENT MEMBRANE (GBM) ANTIGEN(S) WITH AGE AND DISEASE. Sudhir K, Anand, David Olson $\frac{\text { eniamin } H \text {, Landing, Ellin Lieberman, Eva Heuser, }}{\text { U }}$ Div. Nephro Univ. So. Cal. Sch. Med., Child. Hosp. Los Angeles, GBM of patients Dept. Pathology, Los Angoles.
(McCoy at ants with Alport Syndrome (AS) does not bind anti( ing kidney biopsies of AS suspect children with antiGBM was eval(Groups $1-111$ ) $\mathbf{~ K i d n e y s ~ a u t o p s i e d ~ p a t i e n t s ~ w i t h o u t ~ r e n a l ~ d i s e a s e ~}$ (Groups $1-11 I$ ) and 3 patients with AS (with characteristic electron microscopic lesions) were treated with serum of a patient with strong ant $\operatorname{GBM}$, then with fluorochromed antilgG. Results were as follows:

1046maturational correlates of nephron structure and FUNCTION DURING DEVELDPMENT. Billy S . Arant, Jr. (Spon. by J. N. Etteldorf), University of Tennessee Center for the Health Sciences, Department of Pediatrics, Memphis. Glomerulo-tubular(GT) relationships in the developing kidney have been characterized as immature, with anatomical and function$a 1$ glomerular preponderance. Previous studies have not differentiated renal immaturity from other possible causes of GT imbalance. Glucose titration experiments were performed in 13 puppies from 2-51 days of age in which volume expansion(VX) was avoided (A), given 20ml/kg 0.9\% saline IV (B) and observed (C). Proximal tubular length( $L$ ) and diameter of Bowman's capsule( $D$ ) were measured by microdisaection studies. ;aximel tubular reabsorption of glucose (TmG) and inulin clearance (Cin) increase with age ( $r^{2} .96$ ) ${ }^{*}$, with dry kidney weight (DKW) ( $\mathrm{r}=.72)^{* *}$ and with $\mathrm{L}(\mathrm{r}=.84)^{*}$. DKW incressed with $L(r=.61)^{* *}$. Sin decreased with $D(r=-.58)^{* *}$. Glucose threahold increased from 133 to $210 \mathrm{mg} / \mathrm{dl}$ from $2-23$ days $(\mathrm{r}=.84$ )* but did not increase thereafter. The pattern of functional splay (S) $<3$ weeks of age was greater than that observed $>3$ weeks. TmG/ Cin( $3.37 \pm .28, \underline{W}+$ SD $)$ did not change with age $(r=.54)$. During B a decrease in Tmi** without change in Cin resulted in a decrease in $\operatorname{TmG} / \operatorname{Cin}(2.97 \pm .67)^{* *}$ and an increase in $S$ at all ages. During $C$, TmG increased, Cin did not change and TmG/Cin incressed to $3.60 \pm$ TmG increased, Cin did not change and TmG/Cin incressed to $3.60 \pm$
$.99^{* *}$, values not different from $A$. $S$ resembled that noted in $A^{-}$ - $99^{* *}$, values not different from $A$. S resembled that noted in $A$
at saturation. It is concluded that increments in TmG, Cin and DKW during development, are related to nephron growth and that GT belance for glucose obtains from birth in the canine kidney whose

SERUM LIPIDS IN UREMIC CHILDREN AND THE RESPONSE TO
NUTRITIONAL SUPPLEMENTATION. Matson C. Arnold. Maria

1047G. Boosalis, Malcolm A. Holi iday. University of California, Department of Pediatrics, San Francisco. The incidence of hyperlipidemia and the effect of dietary facfors on serum lipid values were evalyated in 17 non-nephrotic patients with GFR $<60 \mathrm{ml} / \mathrm{min} / 1.73 \mathrm{~m}^{2}$. The mean serum cholesterol level (C) in 17 children was $214 \pm 50 \mathrm{mg} / \mathrm{dl}$ and the mean serum triglyceride level (TG) in 12 children was $187 \pm 67 \mathrm{mg} / \mathrm{dl}$. $C$ was elevated ( $>230 \mathrm{mg} / \mathrm{dl}$ ) in $22 \%$ and TG ( $>140 \mathrm{mg} / \mathrm{dl}$ ) in $92 \%$ of the children. There was no correlation between lipid levels and GFR, albumin, creatinine or BUN.
Multiple computer diet analyses were obtained before and during nutritional supplementation. Absolute values for calories and grams of protein, carbohydrate (CHO), and fat increased. However, when expressed as a percentage of calories ingested, CHO increased 11\% while fat decreased $8 \%$ and protein remained unchanged. In 16 patients $C$ increased from $207 \pm 38 \mathrm{mg} / \mathrm{dl}$ to $239 \pm 49 \mathrm{mg} / \mathrm{dl}$ ( $\mathrm{p}<0.025$ ) and in 10 patients TG increased from $197 \pm 66 \mathrm{mg} / \mathrm{dl}$ to $215 \mathrm{mg} / \mathrm{dl}$ ( $\mathrm{p}<0.1$ ). C and TG were not related to total calories, $\mathrm{gm} / \mathrm{kg}$ CHO or \% fat ingested. TG was related to $\%$ CHO of total calories ingested. Diet appears to be one of the factors influencing elevated lipid levels in uremic children.

RADIORECEPTOR ASSAY FOR SOMATOMEDIN-A IN UREMIC CHILDREN, Watson C.Arnold, E.Martin Spencer, Knut O.Uthne, Carolyn F.Piel,Malcolm A. Holliday. Univ. of Calif., Department of Pediatrics \& Medicine, San francisco. The suggestion that the low Somatomed in A (SM-A) found in uremic children is due to the presence of a serum inhibitor to the bioassay was investigated using the human placenta radio-receptor assay. Twenty three children with chronic renal failure were divided into 3 groups based on the degree of renal failure

| Group | I | II | III |
| :--- | :---: | :---: | :---: |
| GFR $\left(\mathrm{mI} / \mathrm{min} / 1.7 \mathrm{~mm}^{2}\right)$ | $>50$ | $<50$ | hemodialys is |
| SM-A $\mathrm{U} / \mathrm{ml} \mathrm{\&} \mathrm{SEM}$ | $0.8 \pm 0.09$ | $3.96 \pm .58$ | $9.92 \pm 2.6$ |
| No. of pts. | 3 | 15 | 5 |

In the chlldren in group II, there was no correlation between SM-A and GFR, BUN, creatinine, chronological age, bone age, or serum lipids. A correlation was found to growth expressed as a percentage of expected growth ( $r=0, j \%$ ). A negative correlation was found to transferrin levels ( $\mu<0.01$ ). Six patients ingesting calories < $80 \%$ recommended dietary allowances (RDA) for height age had SM-A levels of $3.03 \pm .68 \mathrm{U} / \mathrm{ml}$. Nine patients ingesting $>80 \% \mathrm{RDA}$ had values of $4.59 \pm .81 \mathrm{U} / \mathrm{mi}(\mathrm{p}<0.05)$. In 3 patients paired SM-A levels rose with caioric supplementations from 3.22 paired SM-A levels rose with caloric supplementations from 3
$\mathrm{U} / \mathrm{ml}$ to $5.1 \mathrm{U} / \mathrm{ml}(p<0.05)$. These findings demonstrate that: 1) SM-A levels are elevated in uremic children, 2) these levels correlate with growth in nnytritional status influences SM-A devthat interferes with BPoassay.

1049 ANTICONVULSANT-INOUCED SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND NEPHROTIC SYNDROME (NS). Andrew de Aronson,
 (Spon. by Burton J, Grositin). The University of Chicago Pritzker School of Medicine, Le Rabida Children's Hospital. Depar

A 3 year old boy was treated with diphenylhydantoin (DPH) ethosuximide (E), and phenobarbital for convulsions following herpes encephalitis. After 3 months of anticonvulsant treatment he developed NS ( 24 hour uri.ve protein-9.1 grams, serum albumin$0.76 \mathrm{gms} . \%$, cholesterol-356 $\mathrm{mg} . \%$ ), positive ANIF ( $1: 800$ ), "suspiciously" positive LE preparation, positive skin blopsy (dermalepidermel IgG), and high total cos inophil count ( 985 - ni 50-250) After withdrawal of DPH and $\varepsilon$ there was gradual resolution of NS and normelization of urine, serum protein, cholesterol, ANIF and eosinophilia. Renal function and serum complement levels remained normal. Corticusteroids were not given.

Although anticonvulsants have been associated with SLE-like syndromes, serologic abnormalities, nephritis or WS, no previously reported patient developed SLE and NS concurrently. The urgency in discontinuing DPH and E prevented our identifying the offending drug. it is likely that this patient sustained a syndrome of drug-induced SLE with immune-mediated reversible glomerulonephritis and NS.

 RENAL HISTOPATHOLOGY AND CLINICAL COURSE OF 53 CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE). Androw Je Aronson, Ronald do Kallen, Burton J. Grossman, phisit Saphyakhalon, $\frac{\text { Roso } T \text {, Ong and }}{\text { Benionin } \mathrm{H}_{0} \text { Spargo }}$ The University of Chicago Pritzker School of Medicine, Le Rabide Children's Hospital, Departments of Pediatrics and Pathology, Chicago, llilinois.53 patients with SLE have been followed for 7 months to 10 years and have undergone at least one renal biopsy (RB). Histopathologic classification of initial RB was: 1 normal, 9 Type 1 (proliferation without deposits). 5 Type 11 (membranous), and 38 Type 111 (proliferation with deposits). Each patient received prednisone, 13 received azathioprine or eyclophosphamide. Subsequent RB or post-mortem examination in 15 showed progression in 4 (1 with Type 1, 2 with Type 11 and 1 with Type 111 ), Improvement in 4 with Type 111 and no significant change in 7. 4 developed renal fallure, 3 of whom expired, 8 died of non-renal causes and 1 is azotemic. The remainder are alive. Chronic renal failure and persistent active renal disease occurred only with Types 11 and 111 . The low incidence of renal fallure (7.5\%) in this large series of patients with SLF despite the preponderance of Type 111 suggests a batter prognosis than previously reported.
