Broadly neutralizing antibodies (bnAbs) targeting epitopes of the influenza virus hemagglutinin (HA) have the potential to provide near universal protection against influenza virus infection¹. However, viral mutants that escape bnAbs have been reported^{2,3}. The identification of bnAb classes that can neutralize viral escape mutants is critical for universal influenza virus vaccine design. Here, we report a distinct class of bnAbs targeting a discrete membrane-proximal anchor epitope of the HA stalk domain. Anchor epitope-targeting antibodies are broadly neutralizing across H1 viruses and can cross-react with pandemic-threat H2 and H5 viruses. Antibodies targeting this anchor epitope utilize a highly restricted repertoire, which encodes for two public binding motifs that make extensive contacts with conserved residues in the fusion peptide. Moreover, anchor epitope-targeting B cells are common in the human memory B cell (MBC) repertoire and were recalled in humans by an oil-in-water adjuvanted chimeric HA (cHA) vaccine^{4,5}, a potential universal influenza virus vaccine. To maximize protection against seasonal and pandemic influenza viruses, vaccines should aim to boost this previously untapped source of bnAbs that are widespread in the human MBC pool.

Antibodies against the major surface glycoprotein hemagglutinin (HA) are critical for providing protection against influenza virus infection^{6,7}. However, most HA-binding antibodies target variable epitopes of the HA head domain, which provide limited protection against antigenically similar influenza virus strains³. Vaccine formulations that preferentially induce antibodies against conserved epitopes of the HA head and stalk domains could provide broad and potent protection against a wide array of influenza viruses. Several leading universal influenza virus candidates are designed to induce antibodies specifically against the stalk domain, but the spectrum of distinct epitopes on the stalk targeted by the human B cell repertoire remains to be determined. By analyzing the specificities of B cells targeting the H1 stalk through the generation of monoclonal antibodies (mAbs), our study reveals a new class of bnAbs against an underappreciated epitope where HA anchors

itself into the viral membrane. Next-generation vaccine platforms should take advantage of this finding to elicit antibodies against the conserved anchor epitope.

Results

Discovery of anchor epitope binding mAbs

To investigate the specificities of HA-specific antibodies, we generated 358 mAbs from plasmablasts and HA⁺ memory B cells (MBCs) isolated from volunteers that were vaccinated against or naturally infected with seasonal influenza viruses or were participants in a phase I clinical trial of cHA vaccine^{4,5}. Of all mAbs tested, nearly half targeted the HA stalk domain, 21% of which targeted the well-characterized central stalk (CS) epitope (Extended Data Fig. 1a). Notably, stalk-binding

mAbs were disproportionately isolated from the infected, 2009 pandemic H1N1 (pH1N1) monovalent inactivated influenza vaccine (MIV), and cHA vaccine cohorts (Extended Data Fig. 1b), as these exposure routes have previously been shown to induce antibody responses against the HA stalk^{5,8,9}. To investigate which epitopes the remaining 79% of stalk-binding mAbs were targeting, we performed negative stain electron microscopy with three non-CR9114¹⁰ competing stalk domain-binding mAbs: 047-09 4F04, 241 IgA 2F04, and 222-1C06. All three mAbs bound an epitope near the anchor of the HA stalk and were oriented at an upward angle towards the epitope (Fig. 1a–b and Extended Data Fig. 1c), suggesting this epitope may be partially obstructed by the lipid membrane and may only be exposed for antibody binding as the HA trimers flex on the membrane. FISW84, a recently identified stalk-binding mAb¹¹, targets an epitope that overlaps with the three identified anchor-binding mAbs (Extended Data Fig. 1d), suggesting the anchor epitope is a common stalk epitope. Moreover, a proximal epitope was previously identified on group 2 viruses that is targeted by mAbs CR8020¹² and CR8043¹³. Despite some overlap, the epitope targeted by the group 2 mAbs was considerably farther up and to the right on the HA stalk relative to the anchor epitope, and mAbs CR8020 and CR8043 targeted the stalk from above (Extended Data Fig. 1e–f), at an angle and positioning more akin to antibodies targeting the CS epitope. MAb binding the CS epitope (CR9114¹⁰ and FI6v3¹⁴) did not have overlapping footprints or compete for HA binding with the anchor-binding 047-09 4F04 mAb in an HA competition assay (Fig. 1c–d). In total, we identified 50 distinct mAbs that competed for binding to the anchor epitope from a total of 21 individuals (Fig. 1d and Extended Data Table 1 and 2). Of these, 34 anchor-binding mAbs from 15 donors were isolated from the cHA vaccine trial (Extended Data Table 1 and 2).

Anchor-binding mAbs were broadly reactive and broadly neutralizing against pre- and post-pandemic H1N1 viruses and a swine-origin H1N2 virus (Fig. 1e and Extended Data Fig. 1g–h). Notably, anchor-binding mAbs had similar neutralizing potency against pH1N1 relative to mAbs against the central stalk epitope (Fig. 1e and Extended Data Fig. 1i–j). Many stalk-targeting antibodies mediate protection via Fc-mediated functions, including antibody-dependent cellular cytotoxicity (ADCC)^{15,16}. Anchor epitope-binding mAbs largely did not possess ADCC activity (15/18; Extended Data Fig. 1k–l), potentially due to the upward angle of approach of anchor-binding antibodies which may position the Fc distantly from effector cells. Despite pan-H1 binding, anchor-targeting mAbs rarely cross-reacted with other HA subtypes tested, including H3, a group 2 subtype, other group 1 subtypes, including H2 and H5, and influenza B viruses (Fig. 1f and Extended Data Fig. 2a). Despite this, 222-1C06 mAb cross-reacted with H2 and H5 HA (Fig. 1g and Extended Data Fig. 2b) and several anchor-binding antibodies could neutralize an H2N2 virus (Extended Data Fig. 2c), suggesting antibodies targeting the anchor epitope can cross-neutralize other group 1 influenza A viruses. We recently demonstrated that bnAbs against the HA stalk are often polyreactive¹⁷, which may limit the activation of B cells expressing bnAbs. Relative to mAbs targeting the central stalk epitope, we identified that anchor-binding mAbs were proportionally less likely to be polyreactive and those that were polyreactive had weaker relative affinity for LPS (Extended Data Fig. 2d–e). These data suggest that although polyreactivity is selected for within the anti-anchor epitope B cell pool, it is not to the same level as B cells against the CS epitope.

H1N1 viruses have acquired several mutations within the HA stalk domain, likely due to antibody selective pressures or to increase stability. To understand whether these mutations affect antibody binding to the anchor epitope, we screened mAbs against naturally occurring and experimentally identified viral escape mutants of mAbs binding to the CS epitope (Extended Data Fig. 2f–g and Extended Data Table 3). Anchor epitope-binding mAbs were mostly unaffected by these mutants whereas most of the CS-binding mAbs showed reduced binding to at least one mutant (Extended Data Fig. 2g). Notably, most mAbs had reduced binding to A388V of HA2, which was recently shown

to preferentially grow in the presence of mAbs against the CS epitope². While A373 is distant from the anchor epitope, the A373V mutation was shown to affect the conformation of the HA stalk², explaining the broad reduction of HA binding by antibodies targeting either stalk epitope. Anchor-binding mAbs only demonstrated a 10–30% reduction in binding (Extended Data Fig. 2g), indicating they are still likely to neutralize viruses carrying the A373V mutation.

To test whether mAbs targeting the anchor epitope were protective *in vivo*, we prophylactically and therapeutically (48 hours after infection) administered a cocktail of 5 mAbs targeting the anchor epitope or the CS epitope to mimic a polyclonal response against these epitopes and infected mice with a lethal dose of a mouse-adapted pH1N1 virus (A/Netherlands/602/2009; Supplementary Table 1). Mice that received a prophylactic or therapeutic anti-anchor cocktail experienced similar weight loss and mortality, with 5 mg/kg dose providing 100% protection (Extended Data Fig. 3a–b). No differences in lung viral titers were detected in mice that received the anti-anchor cocktail prophylactically relative to the negative control mAb administered mice (Extended Data Fig. 3c). Anti-stalk antibodies do not provide sterilizing immunity but are known to neutralize subsequent rounds and limit disease progression¹⁸. As a result, lung viral titers do not necessarily reflect protection from morbidity and mortality. Lastly, anti-anchor cocktail given prophylactically provided 70% protection against lethal A/Fort Monmouth/1/1947 infection (Extended Data Fig. 3d), a virus that circulated prior to the birth of any of the donors in our study (Extended Data Table 1). Since anchor-binding mAbs do not engage in ADCC for the most part, antibodies targeting the anchor epitope likely provide protection *in vivo* through direct neutralization of virus. Together, these data indicate that antibodies against the anchor epitope are pan-H1 neutralizing and protective *in vivo*.

Structure of an anchor-binding antibody

All anchor epitope-binding mAbs utilized one of four VH3 genes: VH3-23, VH3-30/VH3-30-3, and VH3-48, in contrast to mAbs targeting the CS epitope which commonly use VH1-69 (Fig. 2a and Extended Data Fig. 4a–b). Anchor epitope-binding mAbs also utilized a highly restricted light chain repertoire, with all mAbs utilizing a combination of VK3-11 or VK3-15 combined with JK4 or JK5 (Fig. 2b and Extended Data Fig. 4c–d). Furthermore, all but one light chain of the anchor-targeting mAbs were clonally related (Extended Data Table 2), indicating the light chains were very similar across mAbs and study participants. We identified four distinct clonal expansions, with one public clone found across two donors (Extended Data Fig. 4e–f and Extended Data Table 2). Anchor epitope- and CS-targeting mAbs exhibited similar levels of somatic hypermutations (Extended Data Fig. 4g). The K-CDR3 length of anchor epitope-binding mAbs was highly restricted, with all K-CDR3s being ten amino acids long (Extended Data Fig. 4h).

To investigate the binding motif of anchor-targeting mAbs, we generated a high-resolution (3.38 Å) cryo-EM structure of 222-1C06 bound to A/California/7/2009 HA (Fig. 2c and Extended Data Fig. 4i–k). The broad paratope of 222-1C06 made extensive contacts across the HA fusion peptide (Fig. 2d–e)¹⁹, which mediates viral membrane fusion with the host membrane. Fusion peptide binding was largely mediated by an NWP motif within the K-CDR3, a Y58 directly following the H-CDR2, and a W99 in the H-CDR3, with these HA-binding motifs acting independently and in combination via an aromatic pocket (Fig. 2f–g and Supplementary Table 2). Moreover, both the K-CDR3 NWP and H-CDR2 Y58 were found in all the anchor-binding mAbs and were germline encoded (Fig. 2h–i), which could have led to the selection of B cells utilizing these variable genes. Notably, FISW84 utilizes VH3-23 and VK3-15 and comparison of the paratopes showed the NWP and Y58 motifs of FISW84 similarly form an aromatic pocket but orient towards the fusion peptide slightly differently than 222-1C06 (Extended Data Fig. 4l). Molecular dynamic (MD) simulations additionally showed that VH3-23 and VH3-30 utilizing mAbs from our study and FISW84 targeted

the HA fusion peptide similarly to the cryo-EM structure of 222-1C06 via the aromatic pocket created by the K-CDR3 NWP and H-CDR2 Y58 motifs albeit at different orientations (Extended Data Fig. 4m). Crucially, MD and cryo-EM analyses revealed numerous intra-Fab interactions of hydrophobic and aromatic amino acids, including p-stacking of K-CDR3-P95 with K-CDR3-W94 and H-CDR2-Y58 that rigidified the paratope (Extended Data Fig. 4n-o and Supplementary Table 3).

Broad analysis of human, swine, and avian H1 viruses revealed the side-chain contacts of 222-1C06 were highly conserved (94-100% conserved; Fig. 2j). In addition, the side-chain contacts were 100% conserved across 100 years of H1N1 virus evolution in humans (Extended Data Fig. 4p). Deep mutational scanning of potential H1 viruses at these contact residues indicated substantial permissibility (Extended Data Fig. 4q), although these mutations appear to not have been selected for in nature (Fig. 2j). The five side-chain contacts of this broad epitope were also highly conserved across group 1 viruses, with the W343 contact being 100% conserved across all group 1 viruses (Fig. 2k). Together, these data reveal B cells targeting the anchor epitope utilized a highly restricted V(D)J gene repertoire, and the specific features within this repertoire made critical and extensive contacts with the conserved anchor epitope.

The anchor epitope is a common target

Due to the restricted repertoire features of anchor-targeting mAbs, we next determined the relative proportion of B cells with these features by interrogating single-cell repertoire sequencing of HA-specific B cells isolated from 20 human participants following cHA vaccination^{4,5}. The cHA vaccine platform is intended to specifically induce antibodies against the stalk domain by retaining the stalk domain of H1 and replacing the head domain of HA with that of an avian subtype, either H8 (prime) or H5 (boost) for this trial^{4,5}. To investigate the proportion of B cells with anchor epitope-binding repertoire features, we selected B cells that used VH3-23/VH3-30/VH3-30-3/VH3-48, VK3-11/VK3-15, JK4/JK5, a 10 amino acid length K-CDR3, and possessed an NWP motif within the K-CDR3. We also segregated B cells expressing VH1-69 and a kappa chain, which are commonly used by B cells targeting the CS epitope. We identified that B cells with features of antibodies binding the anchor epitope were abundant within the human B cell repertoire, with 6% of all B cells identified fitting within this defined repertoire (Fig. 3a). Moreover, all but one participant had at least one B cell with anchor-binding repertoire features (Fig. 3b). Additionally, 32 out of 33 mAbs generated from the selected anchor-targeting B cell list competed for HA binding with 047-09 4F04 (Extended Data Fig. 5a), indicating this population was greatly enriched for anchor-targeting B cells. Moreover, the anchor-binding B cells were highly mutated and were largely class-switched to IgG1 (Extended Data Fig. 5b-c), suggesting these B cells were MBCs that had undergone affinity maturation and class switch recombination. Together, these data indicate that the anchor epitope is a common target of the human MBC repertoire following cHA vaccination.

To confirm that anchor epitope-targeting mAbs were representative of the serum antibody response, we performed electron microscopy polyclonal epitope mapping (EMP²⁰) with serum antibodies from participants 236 and 241 from the 2014 quadrivalent inactivated influenza vaccine (QIV) cohort (Extended Data Table 1). Both participants had detectable antibodies targeting the anchor epitope at days 7 and 14 post vaccination (Fig. 3c; Extended Data Fig. 5d-e). Comparison of anchor epitope-binding polyclonal antibodies (pAbs) identified in participant 241 revealed that 241 IgA 2F04 mAb strongly overlapped with the 241 pAb (Fig. 3d), suggesting the pAb derived from this clonal expansion. Together, these data indicate humoral immunity against the anchor epitope is common within the MBC pool and polyclonal serum antibody response after vaccination.

cHA induces anchor-binding antibodies

To investigate whether participants enrolled in a phase I clinical trial of the cHA vaccine (Fig. 4a) mounted an antibody response against

the anchor and the CS epitope, we adapted the competition ELISA to detect serum antibody responses that could compete for binding with 047-09 4F04 and CR9114, respectively. 3 different vaccine formulations were used in this trial, with participants being primed with either a cH8/1 inactivated influenza vaccine (IIV) with an oil-in-water adjuvant (AS03) or cH8/1 live-attenuated influenza vaccine (LAIV) followed by a boost with a cH5/1 IIV with or without AS03 (Fig. 4a). Only participants that received the IIV+AS03 on either the prime or boost were capable of seroconverting against both the anchor and CS epitopes (Fig. 4b-c and Extended Data Fig. 6a-b). Participants that received the cH8/1 IIV+AS03 prime did not further boost serum antibodies against either stalk epitope after the cH5/1+AS03 boost (Fig. 4c), suggesting these B cells were refractory to continued activation. Serum titers against the anchor and CS epitopes (Extended Data Fig. 6a-b) closely matched that of serum neutralizing titers against a cH6/1N8 virus and an avian-swine H1N1 virus³, suggesting the anchor- and CS-targeting serum antibodies were responsible for neutralization.

All but one participant in the IIV+AS03 groups seroconverted against the anchor epitope (Fig. 4d) and had higher titers against the anchor epitope relative to participants that received the 2009 MIV or seasonal influenza virus vaccines (Fig. 4e). However, the precise role of the cHA immunogen versus the AS03 adjuvant in inducing anti-stalk antibody responses could not be resolved in our study. Notably, those individuals that received the IIV alone had weak plasmablast responses relative to those individuals that received the IIV+AS03⁴, suggesting the oil-in-water adjuvant, not the cHA immunogen, was essential for robust B cell activation and anti-anchor antibody responses. Moreover, considerable pre-existing antibodies may hinder recall of B cells against the stalk. Individuals first exposed to the 2009 pH1N1, a virus for which individuals had low pre-existing humoral immunity, had proportionally more isolated mAbs against the stalk and were more likely to have an anti-anchor mAb than individuals that had repeatedly been exposed to the pH1N1 virus in subsequent influenza seasons (Extended Data Fig. 6c-d), therefore suggesting pre-existing antibodies may limit antibody responses against the HA stalk. Despite robust recall of antibodies against the anchor and CS epitopes by the adjuvanted vaccines, titers decreased one year after vaccination (day 420; Extended Data Fig. 6e-f). Together, these data indicate that the adjuvanted inactivated cHA vaccine can robustly induce antibodies against multiple stalk epitopes, including the anchor.

Headless HA antigens, including mini-HA²¹, are attractive universal influenza virus vaccine antigens, as these antigens lack the immunodominant epitopes of the HA head^{21,22}. However, only 1/50 anchor-binding mAbs bound the mini-HA antigen²¹, whereas all anchor epitope-binding mAbs bound cH6/1 (Extended Data Fig. 6g). Compared to full-length HA, the membrane-proximal region of the mini-HA splays by approximately 14.5 Å²¹, which may disrupt the antigenicity of the anchor epitope. To understand whether anchor epitope-targeting antibodies could bind the mini-HA in a more native setting, we generated a membrane-bound mini-HA and observed that mAbs targeting the anchor and CS epitopes readily bind both the full-length membrane-bound A/California/7/2009 HA (Cal09) and the membrane-bound mini-HA (Extended Data Fig. 6h), indicating the mini-HA is antigenic when natively presented. Further, we demonstrated that anchor epitope-targeting antibodies bound HA with a fibrin but not a GCN4 trimerization domain (Extended Data Fig. 6i), highlighting the trimerization domain selection as an important factor for vaccine design. Together, these data demonstrate native-like HA antigens, such as the cHA vaccine, can recall MBCs targeting the anchor epitope.

Discussion

In this study, we identified a public class of bnAbs targeting an epitope at the anchor of the HA stalk domain near the membrane. The

anchor-targeting mAbs were public clonotypes across participants, with all antibodies possessing two conserved, germline-encoded binding motifs: a Y58 directly following the H-CDR2 and an NWP motif within the K-CDR3. The neutralizing activity of anchor epitope-targeting mAbs against pre- and post-pH1N1 viruses and a swine-origin H1-expressing virus indicates the anchor epitope is an important target for pan-subtype neutralizing antibodies. As two of the last four influenza virus pandemics were caused by H1N1 viruses and a recent report shows antigenically novel H1-expressing viruses commonly spilling over from swine into humans²³, it is critically important to generate pan-H1 vaccines to prevent the next influenza pandemic. Moreover, the ability of anti-anchor antibodies to neutralize an H2 virus and the general conservation of contact residues suggests that anchor-targeting antibodies have the potential to acquire cross-neutralization against group 1 viruses.

Our study highlights an additional broadly protective epitope of the HA stalk and provides guidance on how vaccines can be designed to drive broadly protective antibodies against multiple distinct epitopes, which can work cooperatively to provide optimal protection while avoiding the generation of antibody escape mutants. Notably, studies in the HIV-1 field have shown that bnAb monotherapy can lead to the development of antibody resistant viral variants^{24–26} whereas combination bnAb therapy does not²⁷. Additionally, immune focusing toward a single epitope can lead to the generation and selection of viral escape mutants at these highly conserved epitopes^{2,3,28,29}. Therefore, it is critical that future universal influenza virus vaccines elicit antibodies against multiple conserved epitopes to prevent the generation of bnAb escape viruses.

The angle of approach of anchor-binding mAbs and the proximity of the epitope to the viral membrane suggest this epitope is typically obstructed, limiting antibody recognition and B cell activation. However, membrane-bound HA typically flexes between 0° to 25° and up to 52° on its threefold axis¹¹, suggesting antibodies and B cells can easily access the anchor epitope during this flexing process. Moreover, H1 viruses possess a highly conserved glycosylation site on the HA stalk that lies above the anchor epitope^{11,30}, which may obstruct antibodies from targeting this epitope from above. Similarly, a neutralizing mAb against the Middle East respiratory syndrome coronavirus targets an epitope on S2 from an upward angle to avoid glycans³¹. Therefore, the upward angle of approach may be a common feature of antibodies that recognize epitopes below glycans.

Our study shows that humans have pre-existing immunity against the anchor epitope and influenza virus vaccination can recall MBCs to secrete antibodies against this epitope. However, vaccine HA antigens must have a native-like conformation near the transmembrane domain, as trimer splaying potentially due to the GCN4 trimerization domain ablates antibody binding to the anchor epitope. Moreover, our study reveals that the cHA vaccine strategy recalled MBCs against the anchor and CS epitopes, as these MBCs do not need to compete against MBCs targeting the immunodominant variable HA head epitopes^{3,9,17,32}. Similarly, the mini-HA/headless HA vaccine strategy has the potential to also recall MBCs against multiple epitopes of the HA stalk domain, if displayed natively^{22,33}. The addition of an oil-in-water AS03 adjuvant to the cHA was critical for recalling MBCs against the anchor epitope. Oil-in-water adjuvants largely function to emulsify antigen, which may prevent sequestration of antigen by circulating antibodies, increase delivery of free antigen to lymph nodes, and help stimulate innate immune receptors^{34,35}. Notably, an oil-in-water adjuvanted inactivated H5N1 vaccine induced higher neutralizing antibody titers, antibodies against more HA epitopes, and higher avidity antibodies³⁶. Therefore, the inclusion of oi-in-water adjuvants may play an important role in generating bnAbs and may improve vaccine effectiveness of seasonal influenza vaccines. Together, our study shows that novel influenza vaccination strategies, such as the cHA vaccine with the AS03 adjuvant, have the capability to robustly induce antibodies against the

previously unappreciated anchor epitope and can provide broad protection against H1 viruses.

Methods

Study approvals, cohorts, and human materials

Human peripheral blood mononuclear cells (PBMCs) and serum were obtained from multiple donors from multiple cohorts, which is outlined in Extended Data Table 1. Informed consent was obtained from all participants. All studies were performed with the approval of the University of Chicago Institutional Review Board (IRB; ID #09-043-A). The 2009 pH1N1 infection and 2009 MIV cohorts were also approved by the IRB at Emory University. The chimeric HA vaccine study cohort is identified as clinical trial NCT03300050 and further details on trial design are outlined elsewhere^{4,5}. The study was approved by IRBs at local clinical sites, including Icahn School of Medicine at Mount Sinai, Duke University, and Cincinnati Children's Hospital Medical Center. All experiments performed with mice were done in accordance with the University of Chicago and Icahn School of Medicine at Mount Sinai Institutional Animal Care and Use Committees.

Cell lines

Human Embryonic Kidney HEK293T (female, # CRL-11268), Madin Darby canine kidney (MDCK; female, # CCL-34, NBL-2), human A549 (# CCL-185) cells were purchased and authenticated by the American Type Culture Collection (ATCC). MDCK-SIAT1 cells were generated previously³⁷. All cells were maintained in a humidified atmosphere of 5% CO₂ at 37 °C. HEK293T cells were maintained in Advanced-DMEM supplemented with 2% ultra-low IgG fetal bovine serum (FBS; Invitrogen), 1% L-glutamine (Invitrogen) and 1% antibiotic-antimycotic (Invitrogen). MDCK, MDCK-SIAT1, and A549 cells were maintained in DMEM supplemented with 10% FBS (Invitrogen), 1% L-glutamine (Invitrogen) and 1% penicillin-streptomycin (Invitrogen). Jurkat cells expressing FcγRIIIa and FcγRI with NFAT-driven luciferase reporter gene (#G7010) were acquired and validated by Promega and were directly used for ADCC assays. Cell lines were not authenticated after receiving from suppliers and were not tested for mycoplasma.

Monoclonal antibody production

Monoclonal antibodies were generated as previously described³⁸⁻⁴⁰. Peripheral blood was obtained from each donor approximately 7 days after vaccination or infection or obtained 28+ days post-vaccination. Lymphocytes were isolated and enriched for B cells using RosetteSep. Total PBs (CD3⁺CD19⁺CD27^{hi}CD38^{hi}; all cohorts except 2014 QIV), IgG⁺ PBs (CD3⁺CD19⁺IgM⁺CD27^{hi}CD38^{hi}IgG⁺IgA⁺; 2014 QIV), IgA⁺ PBs (CD3⁺CD19⁺IgM⁺CD27^{hi}CD38^{hi}IgG⁺IgA⁺; 2014 QIV cohort), or HA⁺ bait-sorted MBCs (CD3⁺CD19⁺CD27^{hi}CD38^{hi}HA⁺, for 030-09M1B06) were single-cell sorted into 96-well plates. Immunoglobulin heavy and light chain genes were amplified by reverse transcriptase polymerase chain reaction (RT-PCR), sequenced, cloned into human IgG1, human kappa chain, or human lambda expression vectors, and co-transfected into HEK293T cells. Secreted mAbs were purified from the supernatant using protein A agarose beads. For mAbs generated from the 2014 QIV cohort, mAb names include the original isotype of the sorted PB, and all mAbs were expressed as human IgG1. cH5/1-binding B cells (CD19⁺CD27⁺cH5/1⁺) were sorted from donors 28 days after cH5/1 vaccination (NCT03300050). Cells were sorted with A/California/04/2009 HA probe (for 030-09M1B06) or cH5/1 probe, each with a Y98F mutation to ablate non-specific binding to sialic acids on B cells. MAb heavy chain and light chain sequences were synthesized from single-cell RNA-sequencing data of cH5/1-baited B cells (IDT), and cloned into the human IgG1, human kappa chain, or human lambda expression vectors. B cell clones were determined by aligning all the V(D)J sequences sharing identical progenitor sequences, as predicted by IgBLAST using our in-house software, VGenes. Consensus sequence analysis was performed using WebLogo⁴¹ and sequence alignments were determined using Clustal Omega.

Viruses and recombinant proteins

Influenza viruses used in all assays were grown in-house in specific pathogen free (SPF) eggs, harvested, purified, and titered. Recombinant HA, cHA, and mini-HA were obtained from BEI Resources or generated in-house. Recombinant HA mutant proteins used in Extended Data Fig. 2 were generated with identified mutations from the deep mutational scanning experiments (see below) or with known mutations that have arisen naturally or were identified in other studies^{2,10,42-52} (Extended Data Table 3). All mutations were made on HA from A/California/7/2009 and were expressed in HEK293T cells and purified using Ni-NTA agarose beads (Qiagen).

Antigen-specific ELISA

High protein-binding microtiter plates (Costar) were coated with 8 hemagglutination units (HAU) of virus in carbonate buffer or with recombinant HA, including HA mutants described below, at 2 µg/ml in phosphate-buffered saline (PBS) overnight at 4 °C. Plates were washed the next morning with PBS 0.05% Tween and blocked with PBS containing 20% fetal bovine serum (FBS) for 1 hour at 37 °C. Antibodies were then serially diluted 1:3 starting at 10 µg/ml and incubated for 1.5 hour at 37 °C. Horseradish peroxidase (HRP)-conjugated goat anti-human IgG antibody diluted 1:1000 (Jackson Immuno Research) was used to detect binding of mAbs, and plates were subsequently developed with Super Aquablu ELISA substrate (eBiosciences). Absorbance was measured at 405 nm on a microplate spectrophotometer (BioRad). To standardize the assays, control antibodies with known binding characteristics were included on each plate, and the plates were developed when the absorbance of the control reached 3.0 OD units. All ELISAs were performed in duplicate twice. To define antibodies as targeting the H1 stalk, mAbs were tested for binding to cH5/1, which utilizes the head domain from H5-expressing viruses and the stalk domain from the pH1N1 virus⁵³, and for hemagglutination inhibition (HAI) activity against pH1N1 (A/California/7/2009). MAb that bound the cHA and lacked HAI activity were classified as those binding the HA stalk domain. To classify antigen-specificity, mAbs that did not definitively bind the HA head or stalk are listed as binding unknown HA⁺ epitopes. Affinity measurements, as represented as K_d at a molar concentration (M), were calculated using Prism 9 (Graphpad) by performing a non-linear regression. All experiments were performed in duplicate and technically replicated twice.

Competition ELISAs

Plates were coated with 50 µl of A/California/7/2009 HA at a concentration of 1 µg/ml and incubated overnight at 4 °C. To biotinylate the antibodies with known epitope specificities, CR9114 (CS epitope) and 047-09-4F04 (anchor epitope) were incubated at 4 °C with EZ-Link™ Sulfo-NHS-Biotin (Thermo Scientific) for 24h or 48h prior to use, respectively. After blocking the plates with PBS 20% FBS for 1h at 37 °C, serum samples were incubated (starting dilution of 1:50 for human serum or 20 µg/ml for mAbs) in the coated wells for 2h at room temperature. Either biotinylated CR9114 or 047-09-4F04 was then added at a concentration equal to twice its K_d and incubated in the wells with the serum or mAbs for 2h at room temperature. The biotinylated antibodies were desalted before addition to remove free biotin using Zeba™ spin desalting columns, 7k MWCO (Thermo Scientific). After washing the plates, wells were incubated with HRP-conjugated streptavidin (Southern Biotech) at 37 °C for 1h for detection of the biotinylated antibody. Super Aquablu ELISA substrate (eBiosciences) was then added, and absorbance was measured at 405nm on a microplate spectrophotometer (Bio-Rad). To standardize the assays, biotinylated CR9114 or 047-09-4F04 was incubated in designated wells on each plate without any competing serum or mAb, and data were recorded when the absorbance of these wells reached an optical density (OD) of 1 to 1.5 units. After subtracting background, percent competition by serum samples was

then determined by dividing a sample's observed OD by the OD reached by the positive control, subtracting this value from 1, and multiplying by 100. For the serum data, ODs were log transformed and analyzed by non-linear regression to determine EC_{50} values using Prism software (Graphpad). For Fig. 4 and Extended Data Fig. 5, only donors with serum for all timepoints were included. All experiments were performed in duplicate and technically replicated twice.

Polyreactive ELISAs

High-protein binding microtiter plates (Costar) were coated with 10 μ g/ml calf thymus dsDNA (Thermo Fisher Scientific), 2 μ g/ml *Salmonella enterica* serovar Typhimurium flagellin (Invitrogen), 5 μ g/ml human insulin (Sigma-Aldrich), 10 μ g/ml KLH (Invitrogen), and 10 μ g/ml *Escherichia coli* LPS (Sigma-Aldrich) in PBS. Plates were coated with 10 μ g/ml cardiolipin in 100% ethanol and allowed to dry overnight. Plates were washed with water and blocked with PBS/0.05% Tween/1mM EDTA. MABs were diluted 1 μ g/ml in PBS and serially diluted 4-fold and added to plates for 1.5 hours. Plates were washed and goat anti-human IgG-HRP (Jackson ImmunoResearch) was diluted 1:2000 in PBS/0.05% Tween/1mM EDTA. Plates were washed with water and were blocked with PBS/0.05% Tween/1mM EDTA for 5 minutes. Plates were washed again with water and were developed with Super Aquablu ELISA substrate (eBioscience) until the positive control mAb, 3H9⁵⁴, reached an A_{450} of 3. All experiments were performed in duplicate and technically replicated twice.

Deep mutational scanning for stalk domain mutants

The mutant libraries used herein were previously described⁵⁵. The libraries consist of all single amino-acid mutations to A/WSN/1933 (H1N1). The experiments were performed by using biological triplicate libraries. The mutational antigenic profiling of the 045-09 2B06, a CS epitope-binding mAb, was performed as previously outlined⁵⁶. In brief, 10⁶ TCID₅₀ of two of the virus library biological replicates was diluted in 1ml in IGM (Opti-MEM supplemented with 0.01% FBS, 0.3% BSA, and 100 mg/ml calcium chloride) and incubated with an equal volume of 045-09 2B06 antibody at a final concentration of 50 or 25 μ g/ml for 1.5 hours at 37 °C. MDCK-SIAT1 cells were infected with the virus antibody mixtures. 2 hours post-infection, the media was removed, the cells washed with 1 ml PBS, and 2 ml of fresh IGM was added. 15 hours post-infection, viral RNA was extracted, reverse-transcribed using primers WSNHA-For (5'-AGCAAAAGCAGGGGAAAATAAAAACAAC-3') and WSNHA-Rev (5'-AGTAGAAACAAGGGTGTTCCTTATATTCTG-3'), and PCR amplified according to the barcoded-subamplicon library preparation as previously described⁵⁵. The overall fraction of virions that survive antibody neutralization was estimated using qRT-PCR targeting the viral nucleoprotein (NP) and cellular GAPDH as previously described⁵⁶. Using 10-fold serial dilutions of the virus libraries, we infected cells with no antibody selection to serve as a standard curve of infectivity. qPCR Ct values from the standard curve samples compared to the virus-antibody mix samples are determined for NP and GAPDH. We then generate a linear regression to fit the difference between the NP and GAPDH Ct values for the standard curve samples, and then use this curve to interpolate the fraction surviving for the antibody-virus selection samples. Across the three library replicates the fraction of virus surviving antibody selection was 0.17, 0.1, and 0.14.

Illumina(R) deep sequencing data was analyzed using dms_tools2 version 2.4.12 software package⁵⁷ which can be found at https://github.com/jbloomlab/dms_tools2. All of the computer code used is at https://github.com/jbloomlab/2B06_DMS, and the Jupyter notebook that performs most of the analysis is at https://github.com/jbloomlab/2B06_DMS/blob/master/analysis_notebook.ipynb. The sequencing counts were processed to estimate the differential selection for each mutation, which is the log enrichment of that mutation in the antibody-selected condition versus the control⁵⁶. The numerical measurements of the differential selection that 2B06 imposes on each mutation can be found

here: https://github.com/jbloomlab/2B06_DMS/blob/master/results/diffsel/tidy_diffsel.csv.

Deep mutational scanning for H1 variants

Amino-acid preferences for the hemagglutinin (HA) of A/WSN/1933 (H1N1) were previously determined⁵⁵. Briefly, deep mutational scanning was performed by passaging virus libraries at a low MOI in MDCK-SIAT1 cells. Following deep sequencing of the resulting virus, amino-acid preferences were determined using the Python package *dms_tools* (http://jbloomlab.github.io/dms_tools/), version 1.1.12. This program aligns subamplicon reads to the reference HA sequence, counts the number of mutations at each amino-acid site, and determines amino-acid preferences based on the mutation counts pre- and post- selection.

Microneutralization assays

Microneutralization assays for mAb characterization were carried out as previously described^{58,59}. MDCK cells were maintained in DMEM supplemented with 10% FBS, 1% penicillin-streptomycin, and 1% L-glutamine at 37 °C with 5% CO₂. The day before the experiment, 25,000 MDCK cells were added to each well of a 96-well plate. Serial two-fold dilutions of mAb were mixed with an equal volume of 100 TCID₅₀ of virus for 1 hour and added to MDCK cells for 1 hour at 37 °C. The mixture was removed, and cells were cultured for 20 hours at 37 °C with 1X MEM supplemented with 1 μ g/ml tosyl phenylalanyl chloromethyl ketone (TPCK)-treated trypsin and appropriate mAb concentration. Cells were washed twice with PBS, fixed with 80% ice cold acetone at -20 °C for at least 1 hour, washed 3 times with PBS, blocked for 30 min with 3% BSA-PBS, and then treated for 30 min with 2% H₂O₂. Cells were incubated with a mouse anti-nucleoprotein antibody (1:1000; Millipore) in 3% BSA-PBS for 1 hour at room temperature (RT), followed by goat anti-mouse IgG HRP (1:1000; Southern Biotech) in 3% BSA-PBS for 1 hour at RT. The plates were developed with Super Aquablu ELISA substrate at 405 nm until virus only controls reached an OD of 1. The signal from uninfected wells was averaged to represent 100% inhibition. The signal from infected wells without mAb was averaged to represent 0% inhibition. Duplication wells were used to calculate the mean and SD of neutralization, and inhibitory concentration 50 (IC₅₀) was determined by a sigmoidal dose response curve. The inhibition ratio (%) was calculated as: ((OD Pos. Control - OD Sample) / (OD Pos. Control - OD Neg. Control)) * 100. The final IC₅₀ was determined using Prism software (GraphPad). All experiments were performed in duplicate and technically replicated twice.

H2N2 neutralization assays

Twenty thousand MDCK cells were seeded per well in a 96-well cell culture plate (Corning) and the cells were used the next morning to perform the neutralization assay. Antibody dilutions were prepared starting at 30 μ g/ml with 3-fold subsequent dilutions in 1X MEM. Each respective dilution was mixed with 10,000 PFUs of cold adapted A/Ann Arbor/6/1960 (H2N2) virus for 1 hour at room temperature. After an hour, cells were washed with PBS and 100 μ l of antibody-virus mixture was added onto the cells for 1 hour at 37 °C. Next, antibody-virus mixture was removed and 60 μ l of 1X MEM containing TPCK was added to each well. 60 μ l of each corresponding antibody dilution was also added to each well and the cells were incubated at 33 °C for 3 days. On the 3rd day, a hemagglutination assay was performed using turkey red blood cells to assess the HAU at each antibody dilution.

In vivo challenge infections

MAB cocktails (Extended Data Fig. 2b) were passively transferred into 6- to 8-week-old female BALB/c mice (Jackson Laboratories) by intraperitoneal injection of 0.2, 1, and 5 mg/kg mAb cocktail, which are further detailed in Supplementary Table 1. Negative control mice received 5 mg/kg of the anthrax-specific mAb 003-15D03 as an isotype control. MABs were administered two hours before infection for prophylactic treatment and 48 hours post infection for therapeutic treatment. For

Article

prophylactic mAb studies with A/Netherlands/602/2009 (Extended Data Fig. 3a), mice were anesthetized with isoflurane and intranasally challenged with 10 LD₅₀ of mouse-adapted A/Netherlands/602/2009 H1N1 virus, with 10 µl of virus administered into each nostril (20 µl total). For therapeutic treatment of A/Netherlands/602/2009 and prophylactic treatment of A/Fort Monmouth/1/1947, mice were anesthetized with a ketamine-xylazine-water cocktail (0.15 mg ketamine/kg and 0.03 mg/kg xylazine; 100 ml intraperitoneally) and infected with 10 LD₅₀ of A/Netherlands/602/2009 or A/Fort Monmouth/1/1947. As a read out, survival and weight loss were monitored 1-2 times daily for two weeks. Mice were euthanized upon 25% weight loss or at the end of the experiment (14 days post challenge). 5 mice/condition/experiment with 2 biological replicates were utilized based on a previously performed power analysis. Data were pooled for analysis.

To determine differences in lung viral load, 5 mg/kg of the antibody cocktails were administered prophylactically as described above. Two hours after mAb administration, mice (n = 5 mice/group) were anesthetized and intranasally challenged with 1 LD₅₀ of A/Netherlands/602/2009. Lungs were collected at day 3 and day 6 post infection, homogenized and viral load determined via plaque assay. All experiments were done in accordance with the University of Chicago and Icahn School of Medicine at Mount Sinai Institutional Animal Care and Use Committees. Animals studies were not blinded.

Plaque Assay

For determination of viral load in murine lung tissues a standard plaque assay was performed. Confluent monolayers of MDCK cells were infected with serial dilutions of homogenized lung tissue ranging from 1:10 to 1:1000000 diluted in 1x MEM (1% penicillin/streptomycin antibiotics mix, 1% HEPES, 1% L-Glutamine and 1% sodium-bicarbonate (Gibco)) for 1 hour at 33 °C, with shaking every 15 minutes. Afterwards, an overlay containing 2% Oxoid agar (ThermoFisher), H₂O, 2xMEM, DEAE, and TPCK-treated trypsin was added to the cells. The plates were incubated at 33 °C for 3 days and then fixed with 3.7% paraformaldehyde overnight at 4 °C. Plaques were visualized by immunostaining. Here, the agar overlay was removed and the plates blocked with 3% milk/PBS. The blocking solution was removed and primary antibody (H1N1 guinea pig anti-sera (generated in house)) diluted 1:3000 in 1% milk/PBS was added for 1 hour. The plates were washed 3x with PBS and secondary antibody (anti-mouse IgG H&L peroxidase-conjugated (Rockland) diluted 1:3000 in 1% milk/PBS was added for 1 hour. The plates were washed 3x with PBS and developed by using KPL TrueBlue Peroxidase Substrate (SeraCare).

Antibody-dependent cellular cytotoxicity reporter assay

A549 cells were maintained in DMEM supplemented with 10% FBS, 10 U/ml Penicillin, and 10 mg/ml Streptomycin and were plated in 96-well, white-walled plates (Costar) at 2.5x10⁵ cells/ml overnight at 37 °C with 5% CO₂. The following day, cells were washed with PBS and infected with A/Netherlands/602/2009 at a multiplicity of infection of 5 in Ultra-M-DCK media (Lonza) for 24 hours in the absence of TPCK-treated trypsin. MAbs were serially diluted in assay buffer (RPMI 1640 supplemented with 4% ultra-low IgG FBS; Gibco), starting at 60 µg/ml and diluted 3-fold. Aspirate cell medium and add 25 µl of assay buffer and 25 µl of diluted antibody to each well. Jurkat cells expressing human FcγRIIIa with NFAT-driven luciferase reporter gene (Promega) were diluted to 3x10⁶ cells/ml, 25 µl of cells was added to each well and incubated at 37 °C with 5% CO₂ for 6 hours. Plates were removed from incubator and placed at room temperature for 15 minutes. 75 µl BioGlo luciferase substrate (Promega) was added to each well and luminescence was read immediately using a Syngery H1 hybrid multimode microplate reader (Biotek). EC₅₀ values were determined using Prism 8 (GraphPad).

HA:antibody binding footprint mapping

The footprints of three mAbs (FISW84 (PDB: 6HJQ), CR9114 (PDB: 4FQI), and FI6v3 (PDB: 3ZTN)) were mapped onto one HA protomer

(A/California/4/2009, PDB: 4M4Y) using UCSF Chimera⁶⁰ and Adobe Photoshop. Negative stain EM maps of HA:Fab complexes were aligned in UCSF Chimera and estimated footprints were mapped onto one HA protomer. Individual protomers of the HA trimer are indicated in different shades of gray.

Negative stain EM

Immune complexes were prepared by incubating Fab with HA (A/California/04/2009 with E376K or E376G stabilizing mutations) at greater than 3:1 molar ratio for 2 hours at room temperature (RT). Samples were deposited at -10 µg/mL on glow-discharged, carbon-coated 400 mesh copper grids (Electron Microscopy Sciences, EMS) and stained with 2% w/v uranyl formate. Samples were imaged at 52,000x magnification, 120kV, on a Tecnai Spirit T12 microscope equipped with an Eagle CCD 4k camera (FEI) or 62,000 magnification, 200kV, on a Tecnai T20 microscope equipped with a CMOS 4k camera (TVIPS). Micrographs were collected with Leginon, single particles were processed with Appion, Relion, and XQuartz, and footprints were mapped with UCSF Chimera, and figures were made with UCSF Chimera⁶⁰⁻⁶³.

Cryo-EM

222-1C06 and 045-09 2B05 Fabs were incubated at greater than 3:1 molar ratio with HA (A/California/7/2009, E376K) for 1 hour at room temperature. 045-09 2B05 Fab, targeting the lateral patch, was added to the immune complex to induce particle tumbling and increase angular sampling³. Using a ThermoFisher Vitrobot, the immune complex (0.5 mg/ml) incubated with lauryl maltose neopentyl glycol (5 µM, Anatrace) was deposited onto glow-discharged Au 1.2/1.3 300 mesh grids (Electron Microscopy Sciences), blotted for 7 seconds, and plunge-frozen in liquid ethane. Samples were imaged at 36,000x nominal magnification on a 200 kV Talos Arctica electron microscope (FEI) with a CEITA 4K CMOS camera (FEI, total dose 49.92 e/Å²) and Gatan K2 Summit detector in counting mode. 2243 micrographs were collected, aligned, and CTF-corrected using Leginon, MotionCor2 in Appion, and Patch-CTF in CryoSPARC2, respectively^{61,62,64,65}. In CryoSPARC2, particles were picked using apo HA templates, selected through reference-free 2D classification, and reconstructed through 3D classification and refinement. The final map resolved to a global 3.75 Å resolution with C3 symmetry and 44,224 particles. Figures were made in Prism 8 (GraphPad) and UCSF Chimera⁶⁰.

Model building and refinement

A predicted model of 222-1C06 Fab was generated using abYsis (<http://www.abysis.org/abysis/>) and docked into EM density along with an initial model of CA09 H1 HA + 045-09 2B05 (PDB: 7MEM). The initial model was iteratively refined using COOT and Rosetta^{66,67}. The final model was numbered using the H3 and Kabat numbering schemes. The final model and map were evaluated using MolProbity, EMRinger^{68,69}, Phenix, and the PDB validation server. After modeling the immune complex, we segmented the Fab density from HA in the cryo-EM map and mapped the footprint of the 222-1C06 model in the HA density. Cryo-EM data collection and refinement statistics are included in Extended Data Table 4.

EMPEM

Human serum samples were heat-inactivated at 55 °C for 30min before incubating on Capture Select IgG-Fc (ms) Affinity Matrix (Fisher) to bind IgG at 4 °C for 72 hours on a rotator. Samples with IgG bound to resin were centrifuged at 4,000 rpm and supernatant was collected. IgG samples were washed 3 times with PBS followed by centrifugation to remove supernatant. Samples were buffer exchanged into buffer containing 100mM Tris, 2mM EDTA, and 10mM L-cysteine through centrifugation with Amicon filters, then incubated with papain for 4 hours at 37 °C shaking at 80 rpm. The digestion reactions were quenched with 50mM iodoacetamide, buffer exchanged to TBS, and separated

by size-exclusion chromatography (SEC) with a Superdex 200 increase 10/300 column (GE Healthcare). Fab and undigested IgG were collected and concentrated and 500 µg Fab was complexed with 10 µg HA for 18 hours at room temperature. Reactions were purified by SEC and immune complexes were collected and concentrated. Negative stain EM grids were prepared as described above.

Membrane-bound HA and mAb staining

HEK293T cells were plated into a 6-well plate and transfected overnight with 0.2 µg of plasmid and 10 µg/ml PEI. After 12-16 hours, media was replaced with PFHM-II (Gibco) and cells were rested for 3 days. Transfected cells were trypsinized, washed, and aliquoted. Cells were stained with 10 µg/ml of individual mAbs for 30 minutes. Cells were washed and stained with anti-human IgG Fc-BV421 for 30 minutes. Cells were washed 2 times and run on a BD LSRFortessa and collected with BD FACSDiva software. Data were analyzed using FlowJo v10.

Single-cell RNA-seq and repertoire analysis

cH5/1⁺ memory B cells (CD19⁺CD27⁺HA⁺) were bulk sorted and partitioned into nanoliter-scale Gel Bead-In-Emulsions (GEMs) to achieve single cell resolution using the 10x Genomics Chromium Controller and according to the manufacturer's instruction (10x Genomics). The sorted single cells were processed according to 5' gene expression and B cell Immunoglobulin (Ig) enrichment instruction to prepare the libraries for sequencing. Libraries were sequenced using an Illumina HiSeq 4000 at Northwestern University or an Illumina NextSeq 500 at the University of Chicago. Cellranger Single-Cell Software Suite (version 3.0) was used to perform sample de-multiplexing, barcode processing, and single-cell 5' and V(D)J counting, and Cellranger mkfastq was used to de-multiplex raw base call (BCL) files into sample-specific fastq files. Subsequently, GRCh38-1.2.0 and cellranger-vdj-GRCh38-alta-ensembl-2.0.0 were used as references for the transcriptome and V(D)J assembly, respectively. Cellranger counts and Cellranger vdj package were used to identify gene expression and assemble V(D)J pairs of antibodies.

Single cell datasets were analyzed using Seurat 3 toolkit (Version 3.2.0). We performed conventional pre-process steps for all 20 donors including cell quality control (QC), normalization, identification of highly variable features, data scaling, and linear dimensional reduction. More specifically, we only kept cells with more than 200 and less than 2500 detected genes for QC step. We also filtered out cells with high mitochondrial gene expression using a "softThreshold" function in the R package LinQ-View (Version 0.99)⁷⁰. We normalized the RNA data using conventional log normalization. We identified 2000 highly variable genes for each dataset and performed principle component analysis (PCA) in linear dimensional reduction step. We then integrated all 20 single cell datasets from vaccinated participants to remove batch effects using the Anchor method in Seurat 3. In this analysis, we filtered our dataset and only kept cells with both transcriptome and full length and paired heavy and light chain V(D)J sequences (n=1952). From these cells, we identified a group of "VH1-69/Kappa" B cells that used the VH1-69 gene and kappa light chain, which is enriched for B cells targeting the BN stalk epitope. We also identified a group of "anchor epitope" specific B cells by the following rules: 1) VH locus: VH3-23, VH3-30, VH3-30-3, or VH-3-48; 2) VK locus: VK3-11 or VK3-15; 3) JK locus: JK4 or JK5; 4) K-CDR3 length equal to 10; 5) a "NWP" pattern in K-CDR3 peptide.

HA conservation modeling

Pan-H1 conservation models are based on consensus strains (listed in Supplementary Table 4) of distinct H1 clades isolated from humans, swine, and avian sources, as described in Zhuang et al.⁷¹ and inclusion of the Eurasian swine-like A/swine/Jiangsu/J004/2018²³. To generate the group 1 HA conservation model, we selected one representative sequence for each group 1 HA subtype from FluDB (<https://www.fludb.org/>; Supplementary Table 5) according to a prior study⁷². A multiple sequence alignment from these HA protein sequences was generated

using MUSCLE⁷³ and the conservation of each residue was quantified using an entropy model⁴¹. Seasonal H1 conservation models are based on consensus strains of H1N1 viruses (59 strains total) circulating between 1918-1957 and 1976-2019, which was previously described³. Amino acid alignments and H3 numbering were performed using Liberator⁷⁴ and Burke and Smith HA numbering⁷².

Structure prediction

To predict the structures of the investigated Fv fragments (222-1C06, FISW84, 241 IgA 2F04 and SFV009 3G01) with A/California/4/2009 E47G HA (PDB:7MEM) we applied the program Rosettaantibody^{67,75,76}. The Fvs were protonated using the Protonate 3D tool^{77,78}. Charge neutrality was ensured by utilizing the uniform background plasma approach in AMBER^{79,80}. Using the tleap tool of the AmberTools20⁸¹ package, the structure models were soaked in cubic water boxes of TIP3P water molecules with a minimum wall distance of 10 Å to the protein⁸². Parameters for all antibody models derive from the AMBER force field 14SB⁸³. The Fvs were carefully equilibrated using a multistep equilibration protocol⁸⁴.

Metadynamics simulations

To enhance the sampling of the conformational space, well-tempered bias-exchange metadynamics⁸⁵⁻⁸⁷ simulations were performed in GROMACS^{88,89} with the PLUMED 2 implementation⁹⁰. We chose metadynamics as it enhances sampling on predefined collective variables (CV). The sampling is accelerated by a history-dependent bias potential, which is constructed in the space of the CVs^{85,86,91}. As collective variables, we used a well-established protocol, boosting a linear combination of sine and cosine of the ψ torsion angles of all six CDR loops calculated with functions MATHEVAL and COMBINE implemented in PLUMED 2⁹⁰. As discussed previously, the ψ torsion angle captures conformational transitions comprehensively⁹². The underlying method presented in this paper has been validated in various studies against a large number of experimental results⁹³. The simulations were performed at 300 K in an NpT ensemble using the GPU implementation of the pmemd module⁹⁴ to be as close to the experimental conditions as possible and to obtain the correct density distributions of both protein and water. We used a Gaussian height of 10.0 kJ/mol and a width of 0.3 rad. Gaussian deposition occurred every 1000 steps and a biasfactor of 10 was used. 500 ns of bias-exchange metadynamics simulations were performed for the prepared Fv structures. The resulting trajectories were aligned to the whole Fv and clustered with the program cptraj^{80,95} using the average linkage hierarchical clustering algorithm with a RMSD cut-off criterion of 1.2 Å resulting in a large number of clusters. The cluster representatives for the antibody fragments were equilibrated and simulated for 100 ns using the AMBER 20⁸¹ simulation package.

Molecular dynamics simulations

Molecular dynamics simulations were performed in an NpT ensemble using the pmemd.cuda module of AMBER 20⁸⁰. Bonds involving hydrogen atoms were restrained with the SHAKE algorithm⁹⁶, allowing a time step of 2.0 fs. Atmospheric pressure (1 bar) of the system was set by weak coupling to an external bath using the Berendsen algorithm⁹⁷. The Langevin thermostat⁹⁸ was used to maintain the temperature during simulations at 300 K.

With the obtained trajectories we performed a time-lagged independent component analysis (tICA) using the python library PyEMMA 2 employing a lag time of 10 ns. tICA was applied to identify the slowest movements of the investigated Fab fragments and consequently to obtain a kinetic discretization of the sampled conformational space⁹⁹. Based on the tICA conformational spaces, thermodynamics and kinetics were calculated with a Markov-state model¹⁰⁰ of all 6 CDR loops by using PyEMMA 2. The resulting kinetically dominant ensemble in solution was further used to predict the interactions of H1 with the Fvs. To model the complex and to predict interactions in the binding interface, we

Article

used the crystal structure of the full-length influenza hemagglutinin (PDB:7MEM) as template structure. In addition, the obtained complex structure was further minimized and equilibrated.

Statistical analysis

All statistical analyses were performed using Prism software (Graphpad Version 8 and 9) or R. Sample sizes (n) for the number of mAbs tested are indicated in corresponding figures or in the center of pie graphs. Number of biological repeats for experiments and specific tests for statistical significance used are indicated in the corresponding figure legends. *P* values less than or equal to 0.05 were considered significant. **P* ≤ 0.05, ***P* ≤ 0.01, ****P* ≤ 0.001, *****P* < 0.0001.

Reporting summary

Further information on research design is available in the Nature Research Reporting Summary linked to this paper.

Data availability

Repertoire data generated from single cell RNA-sequencing data is deposited at Mendeley Data (<https://data.mendeley.com/datasets/jzxs489pmk/1>). Accession numbers for all other anchor-targeting mAbs are included in Supplementary Table 6. Electron microscopy maps were deposited to the Electron Microscopy DataBank under accession IDs: D_100025433, D_1000254374, D_1000254375, D_1000254376, D_1000254377, D_1000254378, D_1000254383, D_1000254384, D_1000254385, D_1000254386, D_1000254388, D_1000254379, D_1000254391, and D_1000254382. All next generation sequencing data for 045-09 2B06 deep mutational scanning and for the H1N1 mutational scanning can be found on the Sequence Read Archive under BioProject accession number PRJNA309339. The following Protein Database accession numbers were downloaded and included in the manuscript - 6HJQ, 3SDY, 4NM8, 6HJQ, 4M4Y, 4WE4, 4JTV, 4FQI, 3ZTN, and 7MEM. All source data are included with the manuscript. Source data are provided with this paper.

Data and materials availability

Repertoire data generated from single cell RNA-sequencing data is deposited at Mendeley Data (<https://data.mendeley.com/datasets/jzxs489pmk/1>). Accession numbers for all other anchor-targeting mAbs are included in Supplementary Table 6. Electron microscopy maps were deposited to the Electron Microscopy DataBank under accession IDs: EMD-25634 – EMD-25646. CryoEM map and model of anchor and lateral patch Fabs binding H1 HA were deposited to the RCSB database with accession numbers EMD-25655/PDB 7T3D. All next generation sequencing data for 045-09 2B06 deep mutational scanning and for the H1N1 mutational scanning can be found on the Sequence Read Archive under BioProject accession number PRJNA309339. The following Protein Database accession numbers were downloaded and included in the manuscript - 6HJQ, 3SDY, 4NM8, 6HJQ, 4M4Y, 4WE4, 4JTV, 4FQI, 3ZTN, and 7MEM. Sera from the vaccine cohorts are unique to this study and are not publicly available. All other material is available upon reasonable request to the corresponding authors. Acknowledgements We are thankful to all volunteers who participated in this study. We thank Sarah Andrews, Rafi Ahmed, Jens Wrammert, and Karllynn Neu for initiating studies on the 2009 MIV, 2010 TIV, and 2014 QIV cohorts. We thank Chiara Mariottini, Jodi Feser, Daniel Stadlbauer, and Anna-Karin Palm for their help on the cHA vaccine trial. We thank Ian Wilson for fruitful discussion and feedback on experimental design. We thank Bill Anderson and Hannah Turner for assistance with electron microscopy. We are thankful to the teams at PATH, GSK, Cincinnati Children's Hospital Medical Center, and Duke University for their work on the cHA vaccine trial (NCT03300050). This project was funded in part by the National Institute of Allergy and Infectious Diseases (NIAID; National Institutes of Health grant numbers K99AI159136 (JG), U19AI082724 (PCW), U19AI109946 (PCW), U19AI057266 (PCW), P01AI097092 (PP), R01AI145870-01 (PP), R21AI146529 (LC), and T32AI007244-36 (JH)), the NIAID Centers of Excellence for Influenza Research and Surveillance (CEIRS) grant number HHSN272201400005C (PCW), HHSN272201400008C (LC, FK, AGS, PP), and the NIAID Centers of Excellence for Influenza Research and Response (CEIRR) grant number 75N93019R00028 (PCW, FK, AGS, PP). This work was also partially supported by the NIAID Collaborative Influenza Vaccine Innovation Centers (CIVIC; 75N93019C00051, FK, AGS, PP, ABW, PCW). The cHA vaccine trial and evaluation of immunity thereafter was funded in part by the Bill and Melinda Gates Foundation (OPP1084518). The findings and conclusions contained within are those of the authors and do not necessarily reflect positions or policies of the Gates Foundation. This study was also funded by the Austrian Science Fund grant number P34518 (MLF-Q, KRL).

Author contributions Conceptualization: JG, JH, ABW, PCW; Methodology: JG, JH, HAU, LL, LYL, AWF, MLF-Q, CH, CST, MM, GO, FA, LG, NYZ, SS, MH, JDB, LC; Investigation: JG, JH, HAU, LL, LYL, AWF, MLF-Q, CH, CST, MM, GO, VR, FA, OS, LG, HLD, STR, ATP, MET, DJB, SC, LC; Visualization: JG, JH, HAU, LL, MLF-Q, MM, LG, STR; Funding acquisition: JG, JH, AGS, PP, FK, LC, ABW, PCW; Project administration: JG, JH, CH, AGS, KRL, RN, PP, FK, ABW, PCW; Supervision: JG, JH, ABW, PCW; Writing – original draft: JG, JH; Writing – review & editing: JG, JH, HAU, LL, LYL, CH, CST, MM, GO, AWF, OS, LG, HLD, NYZ, STR, ATP, MET, DJB, SC, SS, MH, AGS, RN, PP, JDB, FK, LC, ABW, PCW.

Competing interests The Icahn School of Medicine at Mount Sinai has submitted patent applications on universal influenza virus vaccines naming AGS, RN, PP, and FK as inventors. The A.G.-S. laboratory has received research support from Pfizer, Senhwa Biosciences, Kenall Manufacturing, Avimex, Johnson & Johnson, Dynavax, 7Hills Pharma, Pharmamar, ImmunityBio, Accurius, Nanocomposix, Hexamer, N-fold LLC, and Merck, outside of the reported work. A.G.-S. has consulting agreements for the following companies involving cash and/or stock: Vivaldi Biosciences, Contrafect, 7Hills Pharma, Avimex, Vaxalto, Pagoda, Accurius, Esperovax, Farmak, Applied Biological Laboratories and Pfizer, outside of the reported work.

Additional information

Supplementary information The online version contains supplementary material available at <https://doi.org/10.1038/s41586-021-04356-8>.

Correspondence and requests for materials should be addressed to Jenna J. Guthmiller, Andrew B. Ward or Patrick C. Wilson.

Peer review information Nature thanks the anonymous reviewers for their contribution to the peer review of this work. Peer review reports are available.

Extended Data Fig. 1 | See next page for caption.

Extended Data Fig. 1 | Binding and neutralization features of anchor epitope-binding mAbs. Related to Fig. 1. a, Proportion of HA* mAbs binding to distinct HA domains (left) and proportion of stalk-binding mAbs binding the CS domain (right). Number in the center of the pie graphs represent the number of mAbs tested. **b,** Proportion of mAbs per cohort that bind the HA stalk domain. **c,** Negative stain 2D class averages of 047-09 4F04, 241 IgA 2F04, and 222-1C06 binding to H1 (A/California/7/2009 E376K HA). **d,** Overlay of 047-09 4F04, 241 IgA 2F04, 222-1C06, and FISW84 (PDB:6HJQ) Fabs binding the anchor epitope of A/California/4/2009 HA. **e,** Overlay of CR8020 (PDB:3SDY), CR8043 (PDB:4NM8), and FISW84 (PDB:6HJQ) modeled on A/California/7/2009 E376G (PDB:4M4Y). **f,** Footprints of anchor mAb 222-1C06 on

H1 (top; PDB: 4M4Y) and CR8020 and CR8043 on H3 (bottom; PDB:4WE4). **g,** Heatmap of apparent affinity (K_d ; M) of anchor-targeting mAbs binding to historical and recent H1N1 viruses. **h,** Neutralization potency of anchor-binding mAbs (n=15) against H1-expressing viruses. **i,** Representative microneutralization curves of anchor- (n=42) and CS-binding (n=29) mAbs against A/California/7/2009. **j,** IC_{50} of anchor- and CS-binding mAbs against A/California/7/2009. **k,** ADCC activity of mAbs targeting the CS and anchor epitopes. Dashed line represents the limit of detection (L.O.D.). **l,** ADCC potency of mAbs targeting the anchor (n=18 mAbs) and CS (n=8 mAbs) epitopes. Data in **h, j,** and **l** are represented as mean $\pm$ S.D. Data in **j** and **l** were analyzed using a two-tailed unpaired non-parametric Mann-Whitney test.

Extended Data Fig. 2 | Anchor-targeting mAb binding to influenza subtype, viral mutants, and polyreactivity antigen panel. Related to Fig. 1. a,

Proportion of anchor- (n=50 mAbs) and CS-targeting mAbs (n=37) binding influenza B viruses and H3N2 viruses. **b,** Negative stain 2D class averages of 222-1C06 binding to H2 (A/Singapore/1/1957), and H5 (A/Indonesia/5/2005). **c,** H2N2 neutralizing data of anchor- (n=11 mAbs) and CS-binding mAbs (n=4) represented as minimum neutralizing concentration. The limit of detection (L.O.D.) is 30 mg/ml. **d,** Proportion of mAbs targeting the anchor (n=50 mAbs) or CS (n=50 mAbs) epitope that are polyreactive. **e,** LPS binding strength, represented as area under the curve (AUC), of polyreactive mAbs targeting the anchor (n=30 mAbs) and central stalk (n=43 mAbs) epitopes. Data are mean $\pm$

S.D. **f** and **g,** Anchor- and CS epitope-binding mAbs were tested for binding to A/California/7/2009 HA with naturally occurring and experimentally determined mutations induced by 045-09 2B06, a CS-binding mAb. **f,** Location of mutations modeled on A/California/4/2009 HA (PDB: 4JTV). Residues in blue are located on HA1 and residues in red are located on HA2. Outlines represent binding footprints of 047-09 4F04 (sky blue) and CR9114 (green). **g,** Heatmap of mAb binding to WT and mutant HAs shown as the proportion of signal relative to mAb binding to the WT HA. Data in **a** and **d** were analyzed using Fisher's Exact tests. Data in **e** were analyzed using a two-tailed unpaired non-parametric Mann-Whitney test.

Extended Data Fig. 3 | See next page for caption.

Extended Data Fig. 3 | Anchor epitope-targeting mAbs are potentially protective *in vivo* and lack ADCC activity. Related to Fig. 1. a-b, Mice were prophylactically (2 hours prior to infection; **a**) or therapeutically (48 hours after infection; **b**) administered i.p. a cocktail of mAbs (n=5 mAbs/cocktail) against the anchor- or CS-, or an anthrax-specific antibody. Mice were infected with 10 LD₅₀ of A/Netherlands/602/2009 H1N1. Weight loss (top) and survival (bottom) of mice in each treatment group. **c**, Lung viral titers of mice in each prophylactic treatment group infected with 1 LD₅₀ of A/Netherlands/602/2009. dpi, days post infection. **d**, Mice were prophylactically (2 hours prior to infection) administered i.p. a cocktail of mAbs (n=5 mAbs/cocktail) against the

anchor- or CS-, or an anthrax-specific antibody. Mice were infected with 10 LD₅₀ of A/Fort Monmouth/1/1947 H1N1. Weight loss (top) and survival (bottom) of mice in each treatment group. For **a**, **b**, and **d**, 10 mice per treatment group were used and data are pooled from two independent experiments. For **c**, 5 mice per treatment group and timepoint were used except for anchor cocktail group at dpi 3 only 4 mice were used. Data in **a**, **b**, and **d** are represented as mean ± S.D and data in **c** are represented by mean ± S.E.M. Kaplan-Meier curves in **a**, **b**, **d** were analyzed using a Log-rank Mantel-Cox test, and data in **c** were analyzed using multiple two-tailed unpaired non-parametric Kruskal-Wallis tests.

Extended Data Fig. 4 | See next page for caption.

Article

Extended Data Fig. 4 | Additional repertoire and structural features of mAbs binding the anchor epitope. Related to Fig. 2. a, VH locus usage by anchor- (n=52 mAbs) and CS-binding mAbs (n=37 mAbs). **b**, VH1 gene usage of mAbs targeting the CS epitope. **c**, VK locus usage by anchor- (n=52 mAbs) and CS-binding mAbs (n=37 mAbs). **d**, JK gene usage by anchor epitope-binding mAbs. **e**, Clonal expansions of anchor epitope-targeting mAbs. Numbers indicate heavy and light chain pairings, which are described in Extended Data Table 2. **f**, Heavy and light chain sequences of the public clone. **g** and **h**, Mutations (**g**) and CDR3 amino acid (AA) lengths (**h**) of heavy and light chains of mAbs binding the anchor (n=52 mAbs) or CS (n=37 mAbs) epitopes. Data are mean $\pm$ S.D. **i**, Cryo-EM map of 222-1C06 binding to A/California/7/2009 E376K HA. **j** and **k**, Local resolution (**j**) and Fourier Shell Correlation (**k**) of 222-1C06 binding to HA. **l**, Aromatic pockets of 222-1C06 binding A/California/7/2009 E376K and FISW84 binding to A/duck/Alberta/35/1976 (PDB:6HJQ; top) and

overlay of epitope:paratope interaction (bottom). **m**, MD simulations demonstrating the K-CDR3 NWP and H-CDR2 Y58 motifs of 222-1C06, FISW84, 241 IgA 2F04, and SFV009 3G01 binding to HA A/California/7/2009 HA. For left-hand panels in **l** and all panels in **m**, HA epitope contact residues (maroon) and heavy chain (green) and light chain (yellow) antibody contact residues of anchor mAb paratopes. Peach highlighted amino acids represent the fusion peptide of HA2. **n**, Fab-Fab interactions of the aromatic pocket of 222-1C06. **o**, MD simulation of the paratope flexibility of 222-1C06, highlighting the p-stacking of H-CDR2 and K-CDR3. **p**, Conservation of side-chain contacts of 222-1C06 across seasonal human H1N1 viruses circulating between 1918-2019. **q**, Deep mutational scanning of the side-chain contacts of 222-1C06. Data in **a** and **c** were analyzed using a Chi-square test, and data in **g** and **h** were analyzed by two-tailed unpaired non-parametric Mann-Whitney tests.

Extended Data Fig. 5 | Features of anchor-targeting MBCs and EMP2D classes. Related to Fig. 3. a, 33 mAbs with anchor epitope-binding mAb repertoire features were generated and tested for competing for binding with 047-09 4F04. **b-c**, Number of heavy chain mutations (**b**) and isotype usage (**c**) of B cells with repertoire features of anchor-binding mAbs ($n=119$ cells) or utilize VH1-69/kappa ($n=365$ cells). **d-e**, 2D class averages of pAbs from donors 236 (**d**)

and 241 (**e**) at days 7 and 14 post immunization binding to A/Michigan/45/2015 HA. The last row of 2D classes in **d** is HA monomer complexes processed independently from trimer complexes. Data in **b** are represented as mean $\pm$ S.D. Data in **b** were analyzed using a two-tailed paired non-parametric Wilcoxon matched-pairs signed rank test.

Extended Data Fig. 6 | See next page for caption.

Extended Data Fig. 6 | Serum antibody kinetics of anchor- and CS-epitope binding antibodies after cHA vaccination and mAb binding to recombinant HAs. Related to Fig. 4. a-b, EC50s of serum antibodies

competing for binding with 047-094F04 for binding to the anchor epitope (**a**) and CR9114 for binding to the CS epitope (**b**). **a-b**, Kinetics of serum antibody responses against the anchor (**a**) and CS (**b**) epitopes. Data are mean + S.D. **c-d**, Proportion of stalk⁺ mAbs per donor (**c**) or proportion of donors with an isolated anchor mAb (**d**) upon first exposure to the pH1N1 virus (2009 MIV cohort) relative to donors who have repeatedly been exposed to pH1N1 (2010 TIV and 2014 QIV). Data in **c** are mean ± S.D. Data in **c** includes only donors with an isolated anti-stalk mAb, whereas **d** includes all donors. **e-f**, Antibody titers (EC₅₀) of serum antibodies collected on day 113 and day 420 against the anchor epitope (**e**) and the CS epitope (**f**). Lines connect titers from the same donor and each pair of symbols represents one donor. **g**, Proportion of anchor epitope-binding mAbs binding to cHA (cH6/1) or mini-HA (n=50).

h, Representative flow cytometry plots of mAbs binding to A/California/7/2009 Cal09 HA and mini-HA (left) and geometric mean fluorescence intensity (gMFI) of mAbs binding to Cal09 and mini-HA (right). Data represent the mean ± S.D. and each symbol represents an individual mAb. **i**, Proportion of anchor epitope-targeting mAbs binding to A/California/7/2009 recombinant HA with a GCN4 or fibrin trimerization domain (n=50). For data in **a**, **b**, **e**, and **f**, Group 1 n=10 participants, group 2 n=7 participants, group 4 n=7 participants, group 3&5 n=6. For data in **c**, first exposure n=7 donors and repeated exposure n=4 donors. For data in **d**, first exposure n=10 donors and repeated exposure n=13 donors. Data in **a** and **b** were analyzed using a two-tailed two-way ANOVA testing for simple effects within rows, data in **c** and **h** were analyzed using a two-tailed unpaired non-parametric Mann-Whitney test, data in **d**, **g**, and **i** were analyzed using Fisher's Exact test, and data in **c** and **d** were analyzed using a two-tailed paired non-parametric Wilcoxon matched-pairs signed rank test. See also Supplementary Fig. 1 for gating strategy for panel **h**.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our [Editorial Policies](#) and the [Editorial Policy Checklist](#).

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a Confirmed

☐	☒	The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement
☐	☒	A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
☐	☒	The statistical test(s) used AND whether they are one- or two-sided
<i>Only common tests should be described solely by name; describe more complex techniques in the Methods section.</i>
☒	☐	A description of all covariates tested
☒	☐	A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
☐	☒	A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
☐	☒	For null hypothesis testing, the test statistic (e.g. F , t , r) with confidence intervals, effect sizes, degrees of freedom and P value noted
<i>Give P values as exact values whenever suitable.</i>
☒	☐	For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
☒	☐	For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
☒	☐	Estimates of effect sizes (e.g. Cohen's d , Pearson's r), indicating how they were calculated

Our web collection on [statistics for biologists](#) contains articles on many of the points above.

Software and code

Policy information about [availability of computer code](#)

Data collection Software - Legion beta and v3.2, Appion beta

Data analysis Code - dms_tools2 version 2.4.12, dms_tools version 1.1.12
Software - Prism 8, Prism 9, VGene (beta), Librator (beta), Cellrander Single-Cell Software suite v3.0, Seurat 3 v3.2.0, LinQ-View v0.99, WebLogo v2.8.2, UCSF Chimera 1.14, Pymol v2.3.4, Rosettaantibody v2021, MOE v2020, AMBER v20, GROMACS 2019.2 with plumed-2.5.2., PyEMMA v2.5.7, FlowJo v10, MotionCor v2, Relion v3.0, XQuartz v2.7.11, abYsis v3.4.1, Rosetta 2020.03.61102, coot 0.9-pre EL, CryoSPARC 3.2.0, Phenix 1.17.1-3660, Clustal Omega (<https://www.ebi.ac.uk/Tools/msa/clustalo/>).

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio [guidelines for submitting code & software](#) for further information.

Data

Policy information about [availability of data](#)

All manuscripts must include a [data availability statement](#). This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our [policy](#)

Repertoire data generated from single cell RNA-sequencing data is deposited at Mendeley Data (<https://data.mendeley.com/datasets/jzsz489pmk/1>). Accession numbers for all other anchor-targeting mAbs are included in Supplemental Table 1. Electron microscopy maps were deposited to the Electron Microscopy DataBank under accession IDs: D_100025433, D_1000254374, D_1000254375, D_1000254376, D_1000254377, D_1000254378, D_1000254383, D_1000254384,

D_1000254385, D_1000254386, D_1000254388, D_1000254379, D_1000254391, and D_1000254382. All next generation sequencing data for 045-09 2B06 deep mutational scanning and for the H1N1 mutational scanning can be found on the Sequence Read Archive under BioProject accession number PRJNA309339. The following Protein Database accession numbers were downloaded and included in the manuscript - 6HJQ, 3SDY, 4NM8, 6HJQ, 4M4Y, 4WE4, 4JTV, 4FQI, 3ZTN, and 7MEM.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

☒ Life sciences ☐ Behavioural & social sciences ☐ Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see nature.com/documents/nr-reporting-summary-flat.pdf

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size	Samples sizes were based on the number of donors and ability to process samples.
Data exclusions	No data were excluded.
Replication	All experiments were performed more than once, except the mouse viral titers. All replications were successful.
Randomization	Recipients for the cHA vaccine arms were randomized. Otherwise, no other experimental groups were used and therefore were not randomized.
Blinding	Serum competition ELISAs in Fig. 4 and Extended Data 6 were blinded. Otherwise, no other blinding was performed.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Materials & experimental systems		Methods

Validation

All commercial antibodies were validated by their manufacturers and were titrated in the lab to determine optimal concentration for experimentation. In-house generated monoclonal antibodies were validated in preliminary ELISAs to A/California/7/2009 H1N1 virus or recombinant H1 or cH5/1 proteins. MAb concentrations were standardized based on the assay and starting concentration is described in methods section.

Eukaryotic cell lines

Policy information about [cell lines](#)

Cell line source(s)

HEK293T cells - ATCC
MDCK cells - ATCC
A549 cells - ATCC
Jurkat cells expressing FcγRIIIa with NFAT-drive luciferase reporter gene - Promega, G7010
MDCK-SIAT1 - generated in 10.1126/science.1187816.

Authentication

Cell lines were authenticated by supplier. No other authentication at the lab level was performed.

Mycoplasma contamination

Cell lines were not tested.

Commonly misidentified lines (See [ICLAC](#) register)

No commonly misidentified cell lines were used in this study.

Animals and other organisms

Policy information about [studies involving animals](#); [ARRIVE guidelines](#) recommended for reporting animal research

Laboratory animals

6-8 week old female Balb/c mice were used for challenge studies. Mice were housed in ABSL-2 conditions with 12-hour light/dark cycles and controlled temperature and humidity.

Wild animals

No wild animals were used in this study

Field-collected samples

No field collected samples were used in this study.

Ethics oversight

Animal experiments were approved by the University of Chicago and Icahn School of Medicine at Mount Sinai IACUCs.

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Human research participants

Policy information about [studies involving human research participants](#)

Population characteristics

For the 2009 MIV, 2009 pH1N1 infection, 2010 TIV, and 2014 QIV cohorts, median age was 30 years old with a range of 20-64. 63% of donors were women. Only birth date, prior influenza virus vaccination status, and sex were obtained or released to the authors for donors within these cohorts.

For the cHA vaccine trial - In Groups 1, 2, and 4 about two-thirds of the subjects were female (70.0%, 66.7%, and 62.5%, respectively), compared to 2/5 (40.0%) in Group 3 and 5/10 (50.0%) in Group 5. Most were non-Hispanic or Latino (80% to 100% per group) and black or African American (66.7% to 87.5%). The median age at enrollment ranged from 26 to 31 years across groups, with minimum age ranging from 18 to 22 and maximum age from 29 to 38. The median weight ranged from 74.7 kg to 84.2 kg and the median height ranged from 165.5 cm to 174.0 cm.

The most common pre-existing conditions across all treatment groups were immune system disorders (24/66, 36.4%), the majority being allergies (seasonal and food), followed by drug hypersensitivity.

No subjects in the placebo Groups 3 and 5 reported taking prior medications and more subjects in Group 1 (5/19, 26.3%) reported taking prior medications compared to Group 2 (1/14, 7.1%) and Group 4 (2/15, 13.3%). The proportions of subjects taking concomitant medications in Groups 1 to 5 were 84.2%, 78.6%, 100%, 60.0% and 80.0%, respectively. The most common, by therapeutic subgroup, were analgesics (20/61, 32.8%), anti-inflammatory and anti rheumatic products (19/61, 31.1%) and sex hormones and modulators of the genital system (18/61, 29.5%).

Recruitment

Participants were recruited from the local community for all cohorts. The target population reflected the community at large. All participants provided informed consent. Donors for the 2009 MIV, 2010 TIV, 2014 QIV, and 2009 pH1N1 infection had been recruited from prior studies from the local community. Participants for the cHA vaccine trial were recruited according to Bernstein et al. Lancet Infectious Disease 2020 and Nachbagauer et al. Nature Medicine 2020. The target population reflected the community at large at each of the participating study sites. Information regarding this trial was provided to potential subjects who have previously participated in vaccine trials conducted at the participating study sites.

Ethics oversight

The study protocol was approved by the IRB at the University of Chicago for all studies, the Emory University for the 2009 pH1N1 infection and 2009 MIV cohorts, and at Icahn School of Medicine at Mount Sinai, Duke University and Cincinnati Children's Hospital Medical Center (CCHMC) for the cHA vaccine study.

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Clinical data

Policy information about [clinical studies](#)

All manuscripts should comply with the ICMJE [guidelines for publication of clinical research](#) and a completed [CONSORT checklist](#) must be included with all submissions.

Clinical trial registration

NCT03300050

Study protocol

Study Protocol can be accessed here - https://clinicaltrials.gov/ProvidedDocs/50/NCT03300050/Prot_000.pdf

 Duke Early Phase Clinical Research Unit, Duke Clinical Research Institute 40 Duke Medicine Circle, Durham, NC 27710
 Studied period:
 Date of first enrollment: 10 October 2017
 Date of last subject completion: 09 August 2019

Outcomes

Primary Objectives
 To assess the reactogenicity and safety through 28 days after each priming dose of cH8/1N1 LAIV (or placebo) and the booster dose of cH5/1N1 IIV +/- AS03A (or placebo) and through 28 days after each dose of IIV (cH8/1N1 IIV + AS03A and cH5/1N1 IIV + AS03A) (or placebo) in terms of rates of solicited local and general adverse events (AEs) through 7 days post-vaccination, unsolicited AEs through 28 days post vaccination, hematological and biochemical laboratory abnormalities up to Visit 13, and medically attended event (MAEs), laboratory-confirmed influenza-like illness (LC-ILI), potential immune-mediated disease (pIMDs), and serious adverse events (SAEs) through Visit 13.
Secondary Objectives
 For this study, serum antibody titers (EC50) for the anchor and central stalk epitopes was determined. Only individuals with samples at d1, 28, 85, 113, and 420 were included in the analysis. Seroconversion was considered when titers increased by 1.5x over pre-vaccine time points (d1 or d85).

Flow Cytometry

Plots

Confirm that:

- ☒ The axis labels state the marker and fluorochrome used (e.g. CD4-FITC).
- ☒ The axis scales are clearly visible. Include numbers along axes only for bottom left plot of group (a 'group' is an analysis of identical markers).
- ☒ All plots are contour plots with outliers or pseudocolor plots.
- ☒ A numerical value for number of cells or percentage (with statistics) is provided.

Methodology

Sample preparation

HEK293T cells were transfected with plasmids to express full length membrane-bound A/California/7/2009 H1 or membrane bound mini-HA. Cells were harvested 4 days later and stained with monoclonal antibodies of interest, which were detected with an anti-human IgG-BV421.

Instrument

BD LSRFortessa

Software

Data Collection - FACSDiva
 Analysis - FlowJo v10

Cell population abundance

Cell population abundance is shown for representative panels and gates are identical across individual datasets.

Gating strategy

Cells were gated on using FSC and SSC. From this gate, mAb+ cells were gated on, based on the secondary Ab only stain. Gating strategy and examples are in Supplemental Fig. 1. For mAb+ gating, histograms are represented.

- ☒ Tick this box to confirm that a figure exemplifying the gating strategy is provided in the Supplementary Information.
