388 **Abstract**

389 Identifying the factors underlying severe COVID-19 in the host genetics is an emerging
390 issue¹⁻⁵. We conducted a genome-wide association study (GWAS) involving 2,393 Japanese
391 COVID-19 cases collected in initial pandemic waves with 3,289 controls, which identified a
392 variant on 5q35 (rs60200309-A) near *DOCK2* associated with severe COVID-19 in younger
393 (<65 ages) patients ($n_{\text{Case}}=440$, odds ratio=2.01, $P=1.2\times 10^{-8}$). This risk allele was prevalent
394 in East Asians but rare in Europeans, showing a value of non-European GWAS. RNA-seq of
395 473 bulk peripheral blood identified decreasing effect of the risk allele on *DOCK2* expression
396 in younger patients. *DOCK2* expression was suppressed in severe forms of COVID-19.
397 Single cell RNA-seq analysis ($n=61$) identified cell type-specific downregulation of *DOCK2*
398 and COVID-19-specific decreasing effects of the risk allele on *DOCK2* in non-classical
399 monocytes. Immunohistochemistry of lung specimens from severe COVID-19 pneumonia
400 showed suppressed *DOCK2*. Moreover, inhibition of *DOCK2* function using CPYPP induced
401 much severer pneumonia in a Syrian hamster model of SARS-CoV-2 infection characterized
402 as weight loss, lung edema, enhanced viral loads, impaired macrophage recruitment and
403 dysregulated type I interferon responses. *DOCK2* plays a key role in host immune response
404 to SARS-CoV-2 infection and development of severe COVID-19, being promising biomarker
405 and therapeutic target.

406 (198 words)

407

408 **Introduction**

409 Coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome
410 coronavirus 2 (SARS-CoV-2) is a serious global public health issue⁶. Although promising
411 vaccines have recently become available, the emergence of SARS-CoV-2 variants may delay
412 the end of this pandemic⁷. COVID-19 manifests a diverse clinical presentation from
413 asymptomatic infection to fatal respiratory/multi-organ failure, in relation to multiple risk
414 factors^{8,9}.

415 Human genetic background influences susceptibility to and/or severity of infectious
416 diseases. The Severe Covid-19 genome-wide association study (GWAS) Group reported a
417 variant at *LZTFL1* on 3p21 with severe COVID-19 risk in Europeans¹. Of interest, these
418 variants demonstrated globally heterogeneous allele frequency spectra, and were rarely
419 present among East Asians².

420 Further GWAS efforts, including COVID-19 Human Genome Initiatives (HGI), have
421 nominated host susceptibility genes³⁻⁵. However, the vast majority of existing studies were
422 carried out on European populations. Considering global diversity of COVID-19 severity,
423 COVID-19 host genetic analysis in non-Europeans should provide novel insights.

424 The Japan COVID-19 Task Force (JCTF) was established in early 2020 as a nation-
425 wide multicenter consortium to overcome the COVID-19 pandemic in Japan (**Extended Data**
426 **Fig. 1, Supplementary Table 1**). Here, we report the result of a large-scale GWAS of COVID-
427 19 in Japanese with systemic comparisons to that in Europeans, which identified the
428 population-specific risk allele at the *DOCK2* region conferring risk of severe COVID-19,
429 especially in younger cases. We further conducted bulk and single cell transcriptomics,
430 immunohistochemical assays of the COVID-19 patients and *in vivo* perturbation in a model
431 organism. Our study found that *DOCK2* suppression is associated with the development of
432 severe COVID-19 in a Syrian hamster model of SARS-CoV-2 infection, and that *DOCK2*-
433 mediated signaling plays a key role in the host immune response to SARS-CoV-2 infection.

434

435 **Results**

436 **Overview of the study participants**

437 In the GWAS, we enrolled unrelated 2,393 patients with COVID-19 who required
438 hospitalization from April 2020 to January 2021 (the 1st to 3rd pandemic waves in Japan),
439 from >100 hospitals participating in JCTF. COVID-19 diagnoses of all cases were confirmed
440 by physicians of each affiliated hospital based on clinical manifestations and a positive PCR
441 test result. As for the control, we enrolled unrelated 3,289 subjects ahead of the COVID-19
442 pandemic who represent a general Japanese population. All the participants were confirmed
443 to be of East Asian origin by a principal component analysis (**Extended Data Fig. 2a,b**).

444 Of the 2,393 COVID-19 cases, 990 ultimately had severe infection as defined by
445 oxygen support, artificial respiration, and/or intensive-care unit hospitalization, while 1,391
446 cases had non-severe diseases. Severity information was not available for the remaining 12.
447 As reported previously^{8,10}, the severe COVID-19 cases were relatively more aged (65.3 ±
448 13.9 years [mean ± SD]) and a higher proportion of males (73.9%), compared with non-
449 severe cases (49.3 ± 19.2 years and 57.2% of males, respectively).

450 In the replication, we enrolled 1,243 severe COVID-19 cases collected from February
451 2021 to September 2021 (the 4th to 5th pandemic waves in Japan) and 3,769 controls.
452 Detailed characteristics of the participants are in **Supplementary Table 2**.

453

454 **COVID-19 GWAS in the Japanese population**

455 The GWAS including all COVID-19 cases yielded no signals satisfying a genome-wide
456 significance threshold ($P < 5.0 \times 10^{-8}$; **Extended Data Fig. 2c**). Cross-population comparisons
457 confirmed risk at multiple COVID-19-associated variants identified in the previous studies^{1,3,5}.
458 Seven out of the 11 reported-positive associations were replicated in our Japanese cohort
459 with $P < 0.05$, including those at *LZTFL1*, *FOXP4*, *TMEM65*, *ABO*, *TAC4*, *DPP9*, and *IFNAR2*
460 (**Fig. 1a** and **Supplementary Table 3**), where the highest ORs were observed in
461 comparisons for severe and younger COVID-19 cases at six of the seven loci. The most
462 significant replication was observed at *FOXP4*, as expected from its higher allele frequency
463 in East Asians than in Europeans³ (OR=1.29, 95% confidence interval [95%CI]=1.13-1.46,
464 $P=9.1 \times 10^{-5}$ for severe COVID-19). By contrast, the risk allele at *LZTFL1* (rs35081325), which
465 showed the strongest association in Europeans, was rare in Japanese. Despite its rare
466 frequency (=0.0013 in controls), we nominally replicated the association with the highest risk
467 in the severe and young COVID-19 (OR=11.8, 95%CI=1.64-85.5, $P=0.014$).

468 We evaluated the impact of HLA variants on COVID-19 risk^{11,12} by *in silico* HLA
469 imputation analysis^{13,14}. We did not observe association signals satisfying the HLA-wide
470 significance threshold ($P < 0.05/2,482$ variants = 2.0×10^{-5} ; **Extended Data Fig. 3** and
471 **Supplementary Table 4**). Among the four major ABO blood types¹⁵, the O blood type was
472 associated with a protective effect ($P < 0.05$), most evidently in severe and younger cases
473 (OR=0.73, 95%CI=0.56-0.93, $P=0.014$; **Extended Data Fig. 4a** and **Supplementary Table**
474 **5**)¹. We found increased risk of the AB blood type, especially in severe cases (OR=1.41,
475 95%CI=1.10-1.81, $P=0.0065$ for all ages). The Japanese is the one with the highest AB blood
476 type frequency¹⁶ (=9.5% in our study), which might have provided power to detect its risk.

477

478 **Cross-population Mendelian randomization**

479 Next, to elucidate the medical conditions that can affect COVID-19 susceptibility, we applied
480 cross-population two-sample Mendelian randomization (MR) analysis (**Supplementary**
481 **Table 6**)¹⁷. In Japanese, as for severe COVID-19, a causal effect was inferred for obesity
482 ($P < 0.0074$; **Extended Data Fig. 4b** and **Supplementary Table 7**). We observed causal
483 inference of asthma, uric acids (UA), and gout, while systemic lupus erythematosus (SLE)
484 showed a protective effect ($P < 0.05$). Hyperuricemia is a risk factors of severe COVID-19 in
485 Japan¹⁰, consistent with our MR findings. In Europeans, we observed significant causal
486 inferences of obesity ($P < 6.2 \times 10^{-6}$)¹⁸, with doubled effect sizes in hospitalized and severe
487 COVID-19 when compared with self-reported COVID-19. Our analysis provided additional
488 evidence of obesity as a risk factor^{8,9}.

489

490 **Population-specific risk allele at *DOCK2***

491 On the basis of the observation that many COVID-19 risk variants confer larger effects in
492 severe and younger cases^{1,3,5,19}, we next performed the analysis by stratifying the subjects
493 according to age and severity of the patients, where severe COVID-19 cases ($n_{\text{Case}}=990$),
494 younger cases (ages < 65, $n_{\text{Case}}=1,484$)⁹, and their combinations ($n_{\text{Case}}=440$) were analyzed.

495 When comparison was made between younger cases with severe COVID-19 and
496 respective controls, we identified a genetic locus on 5q35 that satisfied genome-wide
497 significance ($P = 1.2 \times 10^{-8}$ at rs60200309; **Fig. 1b**). The A allele of the lead SNP (rs60200309),
498 located at an intergenic region downstream of *DOCK2*, was associated with an inflated risk
499 for severe COVID-19 infection (OR=2.01, 95%CI=1.58-2.55, $P=1.2 \times 10^{-8}$; **Table 1** and **Fig.**
500 **1c**). The risk rs60200309-A allele was also associated with an elevated risk of COVID-19 in
501 other comparisons including all COVID-19 cases and controls (OR=1.24; **Supplementary**

502 **Table 8**, and also demonstrated within-case severity analysis (i.e., severe vs non-severe
503 cases; OR=1.27 for all ages and OR=1.90 for ages<65).

504 We then conducted a replication study using additional 1,243 severe cases collected
505 in the latter pandemic waves in Japan and 3,769 controls. We replicated an age-specific
506 nominal risk in the younger COVID-19 cases ($n_{\text{Case}}=833$; OR=1.28, 95%CI=1.02-1.61,
507 $P=0.033$; **Table 1**) compared to all ages (OR=1.00, 95%CI=0.85-1.19, $P=0.96$), while the
508 effect size was smaller than observed in the GWAS cases collected in the initial pandemic
509 waves. We note that decreased severity risk in latter pandemic waves was generally
510 observed for other risk loci (e.g., from OR of 11.8 to 4.4 at *LZTFL1*; regression
511 coefficient=0.57; **Extended Data Fig. 5**). This may suggest that longitudinal shifts of
512 confounding factors along with pandemic waves, such as introduction of therapeutic
513 strategies, high prevalence of vaccination, hospitalization policy changes, and virus strain
514 evolutions, might have mitigated host genetics burdens defined in the initial pandemic waves,
515 while further evaluations would be warranted.

516 We also looked up COVID-19 risk of the *DOCK2* variant in different ancestries (3,138
517 hospitalized COVID-19 cases vs 891,375 controls from the pan-ancestry meta-analysis)^{20,21}.
518 We observed the same directional effect with a marginal association signal (OR=1.73,
519 95%CI=0.95-3.15, $P=0.072$, $\text{MAF}_{\text{Control}}=0.0008$; **Supplementary Table 9**).

520 The variant was prevalent in East Asians ($=0.097$) with the highest frequency in
521 Japanese ($=0.125$) and to a lesser extent in native Americans ($=0.049$), but very rare other
522 ancestry (<0.005 ; **Fig. 1d**). Natural selection screening in Japanese²² suggested marginal
523 positive selection of the variant ($P_{\text{SDS}}=0.051$). Population-specific features of the *DOCK2*
524 variant provide a rationale for COVID-19 host genetic researches in non-Europeans.

525

526 ***DOCK2* downregulation in severe COVID-19**

527 To functionally annotate the *DOCK2* risk variant, we examined eQTL effect by conducting
528 peripheral blood RNA-seq of the COVID-19 patients collected by JTFC ($n=473$). The risk
529 allele at *DOCK2* (rs60200309-A) did not indicate a significant eQTL effect for all patients ($\beta=-$
530 1.07, $P=0.083$; **Fig. 2a**). When stratified by the ages, a negative effect of the risk allele on
531 *DOCK2* expression levels was observed for the younger patients ($n=270$; $\beta=-2.15$, $P=0.0030$
532 for ages <65). This allele did not show any significant eQTL on other surrounding genes (\pm
533 500kb window, $P>0.070$). We observed colocalization between the GWAS and the *DOCK2*

534 eQTL signals (colocalization posterior probability>0.01; **Extended Data Fig. 6** and
535 **Supplementary Table 10**)²³.

536 We performed real-time qPCR-based DE analysis of *DOCK2* between severe and
537 non-severe COVID-19 patients ($n=468$). We found decreased *DOCK2* expression
538 ($=DOCK2/GAPDH$) in the severe patients ($P=0.011$; **Fig. 2b**). Suppression of *DOCK2* was
539 clearer when stratified into younger patients ($P=0.0068$). When the patients were further
540 stratified into asymptomatic, mild, severe, and most severe cases, negative correlation
541 between *DOCK2* expression level and severity grades was observed (**Fig. 2c**). Taken
542 together, *DOCK2* expression is downregulated in peripheral blood cells of severe COVID-19
543 patients, especially in the younger patients, and the risk variant might contribute to severe
544 COVID-19 by suppressing expression of *DOCK2*.

545 *DOCK2* (dedicator of cytokinesis 2) is a Rac activator involved in chemokine signaling,
546 type I interferon (IFN) production, and lymphocyte migration^{24,25}. Elucidation of immune cell-
547 type specific expression profiles is necessary to disentangle roles of *DOCK2* in the biology
548 of COVID-19. We thus conducted single cell RNA sequencing (scRNA-seq) of peripheral
549 blood mononuclear cells (PBMC) obtained from 30 severe COVID-19 cases and 31 healthy
550 controls. We obtained 394,526 high-quality single cells and annotated 12 clusters (**Fig. 2d**
551 and **Extended Data Fig. 7**). When projected, *DOCK2* expression was highest in CD16⁺
552 monocytes (**Fig. 2e**). The percentage of cells expressing *DOCK2* was higher in innate
553 immune cell clusters (monocytes and dendritic cells [DC]) (43.8%) than in other clusters
554 (25.6%; **Fig. 2f**). DE analysis also demonstrated suppressed *DOCK2* expressions in the
555 severe COVID-19 cases in the immune cell clusters as well (FC=0.82, $P=8.3\times 10^{-4}$ for
556 monocytes; FC=0.87, $P=0.050$ for DC; **Fig. 2g**).

557 To disentangle immune cell type specificity, we reconducted clustering and annotation
558 by extracting 63,544 cells belonging to the innate cell clusters (**Fig. 2h** and **Extended Data**
559 **Fig. 7**). Among the classified cell types (classical [CD16⁺CD14⁺⁺], intermediate
560 [CD16⁺CD14⁺], and non-classical [CD16⁺⁺CD14⁺] monotypes, conventional dendritic cells
561 [cDC] and plasmacytoid dendritic cells [pDC]), *DOCK2* expression was evidently high in the
562 non-classical monocytes (CD16⁺⁺CD14⁺ monocytes), of which involvement was implicated in
563 the COVID-19 pathophysiology^{26,27} (**Fig. 2h-j**). DE analysis showed the strongest
564 downregulation of *DOCK2* in non-classical monocytes (FC=0.61, $P=3.2\times 10^{-7}$; **Fig. 2k**).
565 *DOCK2* co-expression gene module²⁸ in non-classical monocytes of the COVID-19 cases
566 implicated the enriched pathways such as immune response signaling pathways and
567 phagocytosis (**Extended Data Fig. 7**). To consolidate evidence on variant-to-function, we

568 assessed single cell eQTL effect of the *DOCK2* risk variant. We found COVID-19 context-
569 specific decreasing dosage effect of the risk variant on *DOCK2* expression in non-classical
570 monocytes ($\beta=-0.21$, $P=0.035$ for COVID-19 and $\beta=0.02$, $P=0.51$ for controls; **Fig. 2l**).

571 We then evaluated biological impacts of *DOCK2* downregulation. In primary cell
572 assays, *DOCK2* inhibition by CPYPP, a *DOCK2*-Rac1 interaction inhibitor²⁹, demonstrated
573 reduced production of IFN- α of pDC under CpG stimulation ($FC=5.5\times 10^{-5}$, $P=0.0038$, $n=3$ per
574 group; **Extended Data Fig. 8a**). pDC is another key innate immune cell involved in COVID-
575 19 pathogenicity³⁰, where *DOCK2* expression was downregulated in COVID-19 cases
576 ($FC=0.79$, $P=0.019$; **Fig. 2k**). Chemotaxis of CD3⁺ T cells under CXCL12 stimulation was
577 blocked ($FC=0.57$, $P=1.0\times 10^{-7}$, $n=19$ per group; **Extended Data Fig. 8b**). The *DOCK2* risk
578 variant-phenotype link of IFN- α production in pDC and chemotaxis of CD3⁺ T cells in primary
579 cell assays was not significant (**Supplementary Fig. 1**). In THP-1 Blue ISG cells, *DOCK2*
580 knockdown showed marked decrease in transcriptional activation of ISG, a surrogate of type
581 I IFN (**Extended Data Fig. 8c-f** and **Supplementary Fig. 2**). These results highlight the
582 important immunological roles of *DOCK2* in COVID-19 exacerbations such as type I IFN
583 immunity and chemotaxis dysregulation, as exemplified by patients with congenital
584 impairment in type I IFN immunity³¹.

585 To confirm involvement of *DOCK2* in COVID-19 pneumonia, we performed
586 immunohistochemical analysis using autopsied human cadaver dead from COVID-19
587 (**Extended Data Fig. 9**). We examined 3 cases of COVID-19 pneumonia, and observed
588 decreased expression of *DOCK2* in lymphocytes and macrophages located in the lung and
589 in hilar lymph node (Sample 1-3; **Fig. 2m**). In two control samples without pneumonia, we did
590 not observe such decrease (Sample 4,5; **Fig. 2n**). *DOCK2* was reported to be suppressed
591 in bronchoalveolar lavage fluid (BALF) cells of COVID-19 patients³², consistent with our
592 findings. We observed loss of *DOCK2* expression in lymphocytes in the non-COVID-19
593 severe pneumonia case (Sample 6), while decrease of *DOCK2* expression was slightly
594 observed in the non-COVID-19 mild pneumonia case (Sample 7). Thus, *DOCK2* expression
595 would be suppressed during severe pneumonia caused by COVID-19. These observations
596 reveal linkage between cell type and tissue-specific downregulation of *DOCK2*, providing a
597 potential value as a biomarker of severe COVID-19.

598

599 **DOCK2 inhibition in Syrian hamster model**

600 To decipher *in vivo* pathogenesis of *DOCK2* in COVID-19, we investigated the effects of
601 *DOCK2* suppression following SARS-CoV-2 infection using a Syrian hamster model

602 (Extended Data Fig. 10a)^{33,34}. Administration of CPYPP (DOCK2 inhibitor) or vehicle
603 (negative control) on mock infected animals did not induce weight loss (Extended Data Fig.
604 10b). When administrated with vehicle, animals infected with SARS-CoV-2 ($n=12$) showed
605 weight loss to 83.3% by dpi 7, and then, the weights recovered up to 97.6% at dpi11. In
606 contrast, when administrated with CPYPP, animals infected with SARS-CoV-2 ($n=13$)
607 showed aberrant weight loss to 79.0% by dpi 7, and weight loss recover was restricted to
608 85.4% at dpi11 (Fig. 3a and Extended Data Fig. 10c). Advanced pulmonary edema was
609 observed in lung of the CPYPP-administrated animals with SARS-CoV-2 infection (dpi 11;
610 Fig. 3b). The largest lung weight (Fig. 3c) and the highest histopathological scoring changes
611 of lung³⁴ (Fig. 3d and Extended Data Fig. 10d-f) were observed at dpi6. In lung
612 immunohistochemistry, migration of CD68 macrophages around alveolar cells was impaired
613 in the CPYPP-administrated animals with infection (Fig. 3d and Extended Data Fig. 10e).
614 On the other hand, lung damage was mild or none at all in vehicle-administrated animals with
615 infection or CPYPP-administrated animals without infection (Fig. 3b-d and Extended Data
616 Fig. 10d-f).

617 Focusing on the deteriorating stages of SARS-CoV-2-induced pneumonia (dpi 3 and
618 6), we assayed SARS-CoV-2 viral loads in various organs. Increased viral loads were
619 observed in nasal swab (dpi 3 and 6), lung (dpi 3), and intestine (dpi 6, $P<0.05$; Fig. 3e) of
620 the CPYPP-administrated animals. Lung cytokine expression profile assay revealed that type
621 I IFN ($IFN-\alpha/\beta$) decreased at dpi 6 and type II IFN ($IFN-\gamma$) increased at dpi3 (Fig. 3f) under
622 CPYPP administration. We also observed that CPYPP administration induced elevated
623 inflammatory cytokine ($IL-6$ at dpi3) and chemokine ($CCL5$ at dpi3) levels. Roles of IFN
624 response in pathogenicity of COVID-19 have been controversial^{31,35,36}. Our observational and
625 interventional findings on *DOCK2* downregulation proposed COVID-19 pneumonia
626 pathophysiology where impaired macrophage recruitment at the site of infection and
627 dysregulated IFN responses resulted in impaired virus elimination and prolonged lung
628 inflammation.

629

630 **Discussion**

631 In this study, we reported GWAS of COVID-19 in Japanese, as one of the initial large-scale
632 COVID-19 host genetic studies in non-Europeans. Our study not only confirmed the presence
633 of multiple genetic variants associated with the COVID-19 risk shared across different
634 populations, but also led the identification of a population-specific risk variant at *DOCK2*,
635 particularly in younger cases with severe COVID-19 collected in the initial pandemic waves.
636 Cross-population MR analysis disclosed a causal inference of a number of complex human
637 traits on COVID-19, such as obesity. Our results highlight roles of the population-specific risk
638 allele host genetic backgrounds, which underscores the need for non-European studies for
639 COVID-19 host genetics. Of interest, autosomal recessive *DOCK2* deficiency is a Mendelian
640 disorder with combined immunodeficiency and severe invasive pneumonia infection
641 (OMIM:#616433)³⁷. Our results should fulfill the genetic and clinical link between Mendelian
642 disorders and common diseases. In the replication study using the cases collected in the
643 latter pandemic waves, we observed significant but relatively smaller effect sizes of severe
644 COVID-19 for the risk variants, including *DOCK2* and *LZTFL1*, identified in the studies based
645 on the cases in the initial waves. How host genetics longitudinally interacts with confounding
646 factors and affects COVID-19 phenotype spectra through the pandemic waves are still
647 elusive. In the near future, a growing number of large-scale COVID-19 host genetics studies
648 of diverse ancestry collection sites and period should be warranted, which contribute to guide
649 a global health strategy against the pandemic.

650 Through the follow-up analyses of GWAS, we showed that *DOCK2*-mediated signaling
651 plays a key role in the response to SARS-CoV-2 infection, suggesting that the hypomorphic
652 *DOCK2* allele is involved in exacerbation of COVID-19, and that *DOCK2* could serve as a
653 potential clinical biomarker predicting severe COVID-19. Bulk and single cell transcriptome
654 analysis of peripheral blood cells identified cell type-specific downregulation of *DOCK2*
655 modulated by COVID-19-specific eQTL effect of the *DOCK2* risk variant in patients with
656 severe COVID-19, which was most evident in innate immune cells including non-classical
657 monocytes and pDC. Nevertheless, causal inference of the COVID-19-specific eQTL on
658 COVID-19 severity could be circular. Potentially, the risk variant induces *DOCK2*
659 downregulation in early phase of infection. Immunohistochemical analysis showed
660 suppressed *DOCK2* in lung of COVID-19 pneumonia. *In vivo* suppression of *DOCK2* by
661 CPYPP following SARS-CoV-2 infection in the Syrian hamster model resulted in severe
662 COVID-19 pneumonia highlighted as impaired migration of macrophages and dysregulation
663 of IFN response. We note the possibility that CPYPP is not specific to *DOCK2* and inhibits

664 other DOCK family genes. Alternatively, *DOCK2* boosting assays are warranted to ideally
665 provide an evidence of its role in COVID-19 pathophysiology. Taken together with its critical
666 roles of in immune regulations²⁵, upregulation of *DOCK2* is considered as potential
667 therapeutic strategy of COVID-19. Our results motivate us for further studies linking *DOCK2*
668 to COVID-19 molecular and clinical phenotypes toward our challenge to overcome the
669 pandemic.

ACCELERATED ARTICLE PREVIEW

836 **Main Figure legends**

837

838 **Figure 1. Severe and younger COVID-19 GWAS in the Japanese population**

839 (a) Forest plots of the risk of COVID-19-associated variants in Japanese. Odds ratios of the
840 COVID-19-associated variants in the Japanese population are indicated. (b) A Manhattan
841 plot of the severe and younger COVID-19 GWAS (440 cases and 2,377 controls).
842 Uncorrected P values from GWAS analysis are shown. A dotted line represents the genome-
843 wide significance threshold of $P < 5.0 \times 10^{-8}$. Manhattan and quantile-quantile plots of all
844 GWAS results are in **Extended Data Fig. 2**. (c) A regional association plot at the *DOCK2*
845 locus. Dots represent SNPs with colors according to linkage disequilibrium (r^2) with the lead
846 SNP of rs60200309. (d) Allele frequency spectra of the rs60200309-A allele in the 1000
847 Genomes Project Phase3v5 database.

848

849 **Figure 2. Cell type and tissue-specific expression profile of *DOCK2* and its down-
850 regulation in severe COVID-19**

851 (a) eQTL effect of the COVID-19 risk variant (rs60200309) on *DOCK2* expression levels,
852 measured as TPM using bulk RNA-seq of peripheral blood. The risk allele (rs60200309-A)
853 decreases *DOCK2* levels in cases with ages < 65. (b,c) *DOCK2* differential expression
854 analysis on COVID-19 severity. *DOCK2* expression levels were quantified by qPCR and
855 adjustment with GAPDH. (b) Comparison between severe and non-severe COVID-19 cases.
856 (c) Comparison among the most severe, severe, mild, and asymptomatic cases of COVID-
857 19. (d-k) Results of the PBMC scRNA sequence of severe cases of COVID-19 ($n=30$) and
858 healthy controls ($n=31$). (d) UMAP visualization of all 394,526 cells. (e) Projection of gene
859 expression density of *DOCK2*. Innate immune cell clusters are framed by a red dotted
860 rectangle. (f) Percentages of *DOCK2* expressing cells and their expression levels, and (g)
861 expression changes in differential expression analysis are indicated for six major cell types.
862 (h) Visualization and annotation of the innate immune cell clusters. (i-k) *DOCK2* expression
863 and its expression changes in differential expression analysis in the innate immune cell
864 clusters, corresponding to (e-g). (l) COVID-19 context-specific decreasing eQTL effect of the
865 *DOCK2* risk variant at non-classical monocytes. (m,n) Immunohistochemical analysis for
866 *DOCK2*. Lung and hilar lymph nodes were obtained from COVID-19 pneumonia (Sample 1;
867 left panel) and control (Sample 5; right panel), and stained with anti-*DOCK2* polyclonal
868 antibody. The results of all the samples (Sample 1-7) are in **Extended Data Fig. 9**. In (a-c)

869 and (I), boxes denote the interquartile range (IQR), and the median is shown as horizontal
870 bars. Whiskers extend to 1.5 times the IQR, and outliers are shown as individual points in (a-
871 c) and all samples are shown as individual points in (I). Uncorrected *P* values are shown in
872 (a-c, g, k-l).

873

874 **Figure 3. *In vivo* suppression of DOCK2 in a Syrian hamster model with SARS-CoV-2**
875 **infection**

876 (a) Changes in weight of animals infected with SARS-CoV-2. (b) Representative
877 photographic image of the lung sample, collected after euthanizing the animals at dpi 11. (c)
878 Lung weight changes after infection. (d) Representative lung histopathology and
879 immunohistochemistry of the infected animals at dpi 6. Middle and Right of histopathology
880 show enlarged views of the area circled in black in Left. (Scale bars, 2.5 mm [Left], 1.0 mm
881 [Middle], and 0.25 mm [Right].) In immunohistochemistry for alveolar macrophage, lung
882 tissue was stained with the anti-CD68 mouse monoclonal antibody. (Scale bars, 0.25 mm.)
883 (e) SARS-CoV-2 viral loads at the organs of the infected animals. (f) Lung cytokine
884 expression assays of the infected animals. In (a) and (c), the error bars represent standard
885 error of the mean, and *P* values were determined with two-sided Welch's *t*-test; **P*<0.05;
886 ***P*<0.01; ****P*<0.001. In (e) and (f), boxes denote the interquartile range (IQR), and the
887 median is shown as horizontal bars. Whiskers extend to 1.5 times the IQR, and all animals
888 are shown as individual points. *P* values were determined with two-sided Wilcoxon rank sum
889 test.

890

891

892 **Methods**

893 **Study participants**

894 All the cases affected with COVID-19 were recruited through JCTF. We enrolled the
895 hospitalized cases diagnosed as COVID-19 by physicians using the clinical manifestation
896 and PCR test results, who were recruited at any of the >100 the affiliated hospitals from April
897 2020 to January 2021 (for the GWAS) or from February 2021 to September 2021 (for the
898 replication; **Supplementary Table 1 and 2**). Patients requiring oxygen support, artificial
899 respiration, and/or intensive-care unit (ICU) hospitalization were defined as 'severe COVID-
900 19', while others were defined as 'non-severe COVID-19'. Details of the clinical manifestation
901 including cardiovascular and respiratory comorbidities are provided in **Supplementary Table**
902 **2**. The threshold of 65 years of age was selected according to the clinical management guide
903 in Japan⁹. Control subjects were collected as general Japanese populations at Osaka
904 University and affiliated institutes (for the GWAS and replication) or by the Biobank Japan
905 Project³⁸ (for the replication). Individuals determined to be of non-Japanese origin either of
906 self-reporting or by principal component analysis were excluded as described elsewhere
907 (**Extended Data Fig. 2a**)³⁹. All the participants provided written informed consent as
908 approved by the ethical committees of the affiliated institutes (Keio IRB approval #20200061).

909

910 **GWAS genotyping and quality control**

911 We performed GWAS genotyping of the 2,520 COVID-19 cases and 3,341 controls using
912 Infinium Asian Screening Array (Illumina, USA). We applied stringent quality control (QC)
913 filters to the samples (sample call rate < 0.97, excess heterozygosity of genotypes > mean +
914 3SD, related samples with PI_HAT > 0.175, or outlier samples from East Asian clusters in
915 principal component analysis with 1000 Genomes Project samples), and variants (variant call
916 rate < 0.99, significant call rate differences between cases and controls with $P < 5.0 \times 10^{-8}$,
917 deviation from Hardy-Weinberg equilibrium with $P < 1.0 \times 10^{-6}$, or minor allele count < 5).
918 Details of the QC for the mitochondrial variants are described elsewhere⁴⁰. After QC, we
919 obtained genotype data of 489,539, 15,161, and 217 autosomal, X-chromosomal, and
920 mitochondrial variants, respectively, for 2,393 COVID-19 cases and 3,289 controls.

921

922 **Genome-wide genotype imputation**

923 We used SHAPEIT4 software (version 4.1.2) for haplotype phasing of autosomal genotype
924 data, and SHAPEIT2 software (v2.r904) for X-chromosomal genotype data. After phasing,
925 we used Minimac4 software (version 1.0.1) for genome-wide genotype imputation. We used

926 the population-specific imputation reference panel of Japanese ($n = 1,037$) combined with
927 1000 Genomes Project Phase3v5 samples ($n = 2,504$)²². Imputations of the mitochondrial
928 variants were conducted as described elsewhere⁴⁰, using the population-specific reference
929 panel ($n = 1,037$). We applied post-imputation QC filters of $MAF \geq 0.1\%$ and imputation score
930 (Rsq) > 0.5 , and obtained 13,116,003, 368,566 and 554 variants for autosomal, X-
931 chromosomal, and mitochondrial variants, respectively. We note that the genotypes of the
932 lead variant in the GWAS (rs60200309) were obtained by imputation ($Rsq = 0.88$). We
933 assessed accuracy by comparing the imputed dosages with WGS data for the part of the
934 controls ($n = 236$), and confirmed high concordance rate of 97.5%.

935

936 **Case-control association test**

937 We conducted GWAS of COVID-19 by using logistic regression of the imputed dosages of
938 each of the variants on case-control status, using PLINK2 software (v2.00a3LM AVX2 Intel
939 [6 Jul 2020]). We included sex, age, and the top 5 principal components as covariates in the
940 regression model. We set the genome-wide association significance threshold of $P < 5.0 \times 10^{-8}$.

942

943 **HLA genotype imputation and association test**

944 HLA genotype imputation was performed using DEEP*HLA software (version 1.0), a
945 multitask convolutional deep learning method¹⁴. We used the population-specific imputation
946 reference panel of Japanese ($n = 1,118$), which included both classical and non-classical
947 HLA gene variants for imputation¹³. Before imputation, we removed the overlapping samples
948 between the GWAS controls and the reference panel ($n = 649$), from the GWAS data side.
949 We imputed HLA alleles (2-digit and 4-digit) and the corresponding HLA amino acid
950 polymorphisms, and applied post-imputation QC filters of $MAF \geq 0.5\%$ and imputation score
951 (r^2 in cross-validation) > 0.7 .

952 As for the imputed HLA variants, we conducted (i) association test of binary HLA
953 markers (2-digit and 4-digit HLA alleles, respective amino acid residues) and (ii) an omnibus
954 test of each of the HLA amino acid positions, as described elsewhere¹³. Binary maker test
955 was conducted using the same logistic regression model and covariates as in the GWAS.
956 Omnibus test was conducted by a log likelihood ratio test between the null model and the
957 fitted model, followed by a χ^2 distribution with $m-1$ degree(s) of freedom, where m is the
958 number of the residues. *R* statistical software (version 3.6.0) was used for the HLA

959 association test. We set the HLA-wide significance threshold based on Bonferroni's
960 correction for the number of the HLA tests ($\alpha = 0.05$).

961

962 **Estimation of the ABO blood types and analysis**

963 We estimated the ABO blood types of the GWAS subjects based on the five coding variants
964 at the *ABO* gene (rs8176747, rs8176746, rs8176743, rs7853989, and rs8176719)⁴¹. We
965 phased the haplotypes of these five variants based on the best-guess genotypes obtained
966 by genome-wide imputation, and estimated the ABO blood type as described elsewhere¹⁵.
967 We could unambiguously determine the ABO blood type of 99.1 % of the subjects.

968 Blood group-specific ORs were estimated based on comparisons of A vs AB/B/O, B
969 vs A/AB/O, AB vs A/B/O, and O vs A/AB/B. We conducted a logistic regression analysis
970 including age, sex and the top 5 principal components as covariates. R statistical software
971 (version 3.6.3) was used for the ABO blood type analysis.

972

973 **Cross-population MR analysis**

974 We conducted two-sample MR analysis as described elsewhere^{17,42}. As exposure, we
975 selected a series of clinical states where altered comorbidity with COVID-19 have been
976 discussed. As an outcome phenotype, we utilized the GWAS summary statistics of Japanese
977 (current study) and Europeans (release 5 from COVID-19 HGI³). Lists of the Japanese and
978 European GWAS studies used as the exposure phenotypes are in **Supplementary Table 6**.
979 We extracted the independent lead variants with genome-wide significance (or the proxy
980 variants in linkage disequilibrium $r^2 \geq 0.8$ in the EAS or EUR subjects of the 1000 Genomes
981 Project Phase3v5 databases) from the GWAS results of the exposure phenotypes. We
982 applied the inverse variance weighted (IVW) method using the TwoSampleMR package
983 (version 0.5.5) in R statistical software (version 4.0.2).

984

985 **The replication analysis**

986 We genotyped additional 1,243 severe COVID-19 cases and 3,769 controls using Infinium
987 Asian Screening Array (Illumina, USA). We applied the QC filters and genotype imputation,
988 and conducted case-control analysis of the variant as in the same manner as the GWAS.

989

990 **RNA-seq of peripheral blood of the COVID-19 patients**

991 We incorporated 475 COVID-19 patients collected at the core medical institutes of JCTF and
992 included in the GWAS for the bulk RNA-seq analysis (**Supplementary Table 2**). Isolation of

993 RNA from the peripheral blood of the COVID-19 patients was conducted using RNeasy Mini
994 Kit (Qiagen, USA). Libraries for RNA-seq were prepared using NEBNext® Poly(A) mRNA
995 Magnetic Isolation Module and NEBNext® Ultra™ Directional RNA Library Prep Kit for Illumina
996 (New England BioLabs, USA). RNA-seq was performed using the NovaSeq6000 platform
997 (Illumina, USA) with paired end reads (read length of 100 bp), using S4 Reagent kit (200
998 cycles). We obtained on average 71,724,142±17,527,007 reads per a sample (mean±SD).
999 Sequencing reads were quality-filtered, and adapter removal was performed using the
1000 Trimmomatic (v0.39)⁴³. Alignment to the human reference genome GRCh38/hg38 was
1001 performed using STAR (v2.7.9a)⁴⁴, based on the GENCODE v30 annotation. Gene level
1002 quantification and normalization was using RSEM (v1.3.3)⁴⁵. Transcripts per kilobase million
1003 (TPM) was used as an index of gene quantification. We excluded the two outlier samples in
1004 the PCA plot of the TPM from the analysis ($n = 473$ for the analysis). We quantified 58,825
1005 genes, and adopted the 5,991 genes with the median TPM > 10 for the subsequent analysis.

1006 In the eQTL analysis of the *DOCK2* variant, dosage effects of the risk variant
1007 (rs60200309-A) on the gene expression levels (TPM) were evaluated using linear regression
1008 models with age, sex, severity, the top 10 PCs of the TPM matrix, and the top 5 PCs of the
1009 GWAS data as covariates. The dosage effects of the risk variant on the expression of nearby
1010 genes located within a 500kb window were also evaluated. *R* statistical software (version
1011 3.6.3) was used for the analysis. Colocalization analysis between the GWAS and the *DOCK2*
1012 eQTL signals was conducted using eCAVIAR²³.

1013

1014 **qPCR-based DE analysis on COVID-19 severity**

1015 Real-time qPCR was conducted for the RNA isolated from the peripheral blood of the COVID-
1016 19 patients ($n = 468$). Total RNA was reverse-transcribed using the High-Capacity RNA-to-
1017 cDNA cDNA Kit (Life Technologies). Real-time qPCR was performed using TaqMan® assays
1018 on a 7500 Fast Real-Time PCR system (Applied Biosystems; probe assay ID:
1019 Hs00386045_m1 [*DOCK2*] and Hs99999905_m1 [*GAPDH*]). DE analysis was conducted
1020 between severe and non-severe COVID-19, and across four COVID-19 disease severity
1021 grades, ordered from Asymptomatic > Mild > Severe > Most Severe. Among the severe
1022 COVID-19, patients in ICU or requiring intubation and ventilation were defined as 'Most
1023 Severe' disease, while the rest as 'Severe' disease. Among the non-severe COVID-19,
1024 patients without any symptoms related to COVID-19 were defined as 'Asymptomatic' disease,
1025 while others as 'Mild' disease. The analysis was performed on relative messenger RNA

1026 expression level of *DOCK2* adjusted with *GAPDH* ($= DOCK2/GAPDH$) using linear
1027 regression models with age and sex as covariates in *R* statistical software (version 3.6.3).

1028

1029 **Subjects and specimen collection of PBMC for scRNA-seq**

1030 Peripheral blood samples were obtained from severe COVID-19 patients ($n=30$) and healthy
1031 controls ($n = 31$) collected at Osaka University Graduate School of Medicine. Of the 30
1032 COVID-19 patients, 5 patients were classified as moderate and 25 patients as severe
1033 according to disease severity based on the highest score on the World Health Organization
1034 (WHO) Ordinal Scale for Clinical Improvement ever present (WHO. R&D Blueprint - novel
1035 Coronavirus - COVID-19 Therapeutic Trial Synopsis. 2020.). For both patients with COVID-
1036 19 and healthy controls, blood was collected into heparin tubes and PBMCs were isolated
1037 using Leucosep (Greiner Bio-One) density gradient centrifugation according to the
1038 manufacturer's instructions. Blood was processed within 3 h of collection for all samples, and
1039 stored at $-80\text{ }^{\circ}\text{C}$ until use.

1040

1041 **Droplet-based single-cell sequencing**

1042 Single-cell suspension were processed through the 10x Genomics Chromium Controller (10x
1043 Genomics, USA) following the protocol outlined in the Chromium Single Cell V(D)J Reagent
1044 Kits (v1.1 Chemistry) User Guide. Chromium Next GEM Single Cell 5' Library & Gel Bead
1045 Kit v1.1 (Cat# PN-1000167), Chromium Next GEM Chip G Single Cell Kit (Cat# PN-1000127)
1046 and Single Index Kit T Set A (Cat# PN-1000213) were applied during the process.
1047 Approximately 16,500 live cells per sample were separately loaded into each port of the
1048 Chromium controller without sample mixing to generate 10,000 single-cell gel-bead
1049 emulsions for library preparation and sequencing, according to the manufacturer's
1050 recommendations. Oil droplets of encapsulated single cells and barcoded beads (GEMs)
1051 were subsequently reverse-transcribed in a Veriti Thermal Cycler (Thermo Fisher Scientific),
1052 resulting in cDNA tagged with a cell barcode and unique molecular index (UMI). Next, cDNA
1053 was then amplified to generate single-cell libraries according to the manufacturer's protocol.
1054 Quantification was made with an Agilent Bioanalyzer High Sensitivity DNA assay (Agilent,
1055 High-Sensitivity DNA Kit, Cat# 5067-4626). Subsequently amplified cDNA was enzymatically
1056 fragmented, end-repaired, and polyA tagged. Cleanup/size selection was performed on
1057 amplified cDNA using SPRIselect magnetic beads (Beckman-Coulter, SPRIselect, Cat#
1058 B23317). Next, Illumina sequencing adapters were ligated to the size-selected fragments and
1059 cleaned up using SPRIselect magnetic beads. Finally, sample indices were selected and

1060 amplified, followed by a double-sided size selection using SPRIselect magnetic beads. Final
1061 library quality was assessed using an Agilent Bioanalyzer High Sensitivity DNA assay.
1062 Samples were then sequenced on NovaSeq6000 (Illumina, USA) as paired-end mode (read1:
1063 26bp for cell barcodes, read2: 91bp for RNA reads) to achieve a minimum of 20,000 paired-
1064 end reads per cell for gene expression.

1065

1066 **Alignment, quantification and quality control of scRNA-seq data**

1067 Droplet libraries were processed using Cell Ranger 5.0.0 (10x Genomics, USA). Sequencing
1068 reads were aligned with STAR (v2.7.2a)⁴⁴ using the GRCh38 human reference genome.
1069 Count matrices were built from the resulting BAM files using dropEst⁴⁶. Cells that had fewer
1070 than 1,000 UMIs or greater than 20,000 UMIs, as well as cells that contained greater than
1071 10% of reads from mitochondrial genes or Hemoglobin genes, were considered low quality
1072 and removed from further analysis. Additionally, putative doublets were removed using
1073 Scrublet (v0.2.1) for each sample⁴⁷.

1074

1075 **scRNA-seq computational pipelines and basic analysis**

1076 The R package Seurat (v3.2.2) was used for data scaling, transformation, clustering,
1077 dimensionality reduction, differential expression analysis and most visualization⁴⁸. Data were
1078 scaled and transformed using the SCTransform() function, and linear regression was
1079 performed to remove unwanted variation due to cell quality (% mitochondrial reads). For
1080 integration, we identified 3,000 shared highly variable genes (HVGs) using
1081 SelectIntegrationFeatures() function. Then, we identified 'anchors' between individual
1082 datasets based on these genes using the FindIntegrationAnchors() function and inputted
1083 these anchors into the IntegrateData() function to create a batch-corrected expression matrix
1084 of all cells. Principal component analysis (PCA) and uniform manifold approximation and
1085 projection (UMAP) dimension reduction with 30 principal components were performed⁴⁹. A
1086 nearest-neighbor graph using the 30 dimensions of the PCA reduction was calculated using
1087 FindNeighbors() function, followed by clustering using FindClusters() function.

1088 Cellular identity was determined by finding differentially expressed genes (DEGs) for
1089 each cluster using FindMarkers() function with parameter 'test.use=wilcox', and comparing
1090 those markers to known cell type-specific genes (**Extended Data Fig. 7a**). We obtained 12
1091 cell clusters, which were further confirmed using Azimuth (**Fig. 2d** and **Extended Data Fig.**
1092 **7a,c**)⁵⁰. Six major cell types were defined from 12 clusters as follows; CD4⁺ T cells [CD4T]
1093 and Treg were annotated as CD4T; CD8⁺ T cells [CD8T] and Proliferative T cells [Pro_T]

1094 were annotated as CD8T; natural killer cells [NK] were annotated as NK; B cells [B] and
1095 Plasmablast were annotated as B; CD14⁺monocytes and CD16⁺monocytes were annotated
1096 as monocytes [Mono]; conventional dendritic cells [cDC] and plasmacytoid dendritic cells
1097 [pDC] were annotated as Dendritic cell [DC]. To clarify immune cell type-specific expression
1098 of *DOCK2*, we produced the density plot using `plot_density()` function from *Nebulosa R*
1099 package (v1.0.0)⁵¹, and the dot plot using `DotPlot()` function.

1100 Droplets labeled as innate immune cell clusters (CD14⁺monocytes, CD16⁺monocytes,
1101 cDC, and pDC) were extracted and reintegrated for further subclustering using the same
1102 procedure as described above except using 2,000 shared HVGs. After integration, clustering
1103 and cluster annotation (**Extended Data Fig. 7b**) were performed as described above.

1104

1105 **DE analysis using scRNA-seq data**

1106 Differential gene expression analysis was performed between severe COVID-19 patients and
1107 healthy controls in each cell type. Donor pseudo-bulk samples were first created by
1108 aggregating gene counts for each cell type within each sample. Genes which expression rate
1109 was more than 10% in either COVID-19 patients or healthy controls in each cell type were
1110 included in the analysis. Differential gene expression testing was performed using an NB
1111 GLM implemented in the Bioconductor package *edgeR* (v3.32.0)⁵².

1112

1113 ***DOCK2* co-expression analysis and GO enrichment analysis**

1114 We applied the weighted gene co-expression network analysis (WGCNA) algorithm²⁸ to
1115 evaluate co-expressed genes with *DOCK2* in COVID-19. Pseudo-bulk normalized data of
1116 non-classical monocytes in the COVID-19 patients using *scran* (v1.18.5)⁵³ was used for
1117 WGCNA analysis, and genes were selected if they were expressed in more than 1% of cells
1118 in non-classical monocytes of the COVID-19 patients. We calculated the adjacency with a
1119 “unsigned network” option and soft threshold power with the adjacency matrix set to 5,
1120 created Topological Overlap Matrix by `TOMsimilarity`, calculated the gene tree by `hclust`
1121 against `1 - TOM` with method = “average”, and conducted a dynamic tree cut with the following
1122 parameters; `deepSplit = 4`, `minClusterSize = 30`. We performed GO enrichment analysis of
1123 *DOCK2* co-expression gene module using the function `enrichGO` (`pvalueCutoff = 0.01`,
1124 `pAdjustMethod = “BH”`, `OrgDb = “org.Hs.eg.db”`, `ont = “BP”`) of *ClusterProfiler* (v3.14.3)⁵⁴.

1125

1126 **Single-cell eQTL analysis of the *DOCK2* risk variant**

1127 We applied pseudo-bulk approach for single-cell eQTL analysis. First, we performed single-
1128 cell-level normalization using scran (v1.18.5)⁵³. Gene expression per cell type per sample
1129 was then calculated as the mean of log₂-transformed counts-per-cell-normalized expression
1130 across cells. For principal component (PC) analysis, genes were adopted if they were
1131 expressed (UMI count >0) in more than 1% of cells in non-classical monocytes.

1132 In the eQTL analysis of the *DOCK2* variant, dosage effects of the risk variant
1133 (rs60200309-A) on the gene expression were evaluated using linear regression models with
1134 age, sex, disease severity (included only in COVID-19 analysis) and the top 2 PCs of the
1135 gene expression as covariates. *R* statistical software (version 4.0.2) was used for the analysis.

1136

1137 **IFN- α production assay using primary blood cells**

1138 PBMC were isolated from the blood of 3 healthy donors by Lymphoprep density gradient.
1139 pDC cells were purified by negative selection using the Plasmacytoid Dendritic Cell Isolation
1140 Kit II (Miltenyi Biotec, USA). To evaluate interferon- α production ability, sorted pDC cells
1141 were stimulated with 30 μ g/ml CpG-A ODN (D35; Gene Design, Japan) or control. Interferon-
1142 α was evaluated 12 hr after stimulation using VeriKine-HS Human Interferon Alpha All
1143 Subtype TCM ELISA Kit (PBL, USA). Differences of IFN α production between the groups
1144 were evaluated using paired *t*-test.

1145

1146 **Chemotaxis assay using primary blood cells**

1147 PBMC were isolated from the blood of 19 healthy donors by Lymphoprep density gradient.
1148 CD3⁺ T cells were sorted by magnetic activated cell sorting (MACS). CD3⁺ T cells (1.0×10^5)
1149 in 100 μ l RPMI + 0.5% BSA medium \pm CPYPP (100 μ M; Tocris, UK) were placed in the upper
1150 chambers of Transwell (5 μ m pore size; Coaster, USA). The lower chambers were filled with
1151 400 μ l RPMI medium supplemented with CXCL12 (100 ng/ml; R&D Systems, USA) and
1152 incubated at 37°C for 2 hours. The cells that migrated to the lower chambers were collected
1153 and analyzed using FACS. The following monoclonal antibodies were used for FACS
1154 analysis: anti-human CD3 (UCHT1; BD Biosciences, USA) and CD4 (SK3; BD Biosciences,
1155 USA) antibodies. Dead cells were excluded using zombie dyes (BioLegend; USA). Events
1156 were acquired with a LSR Fortessa (BD Biosciences, USA) and analyzed with FlowJo
1157 software (BD Biosciences, USA). Differences of chemotaxis between CXCL12 groups and
1158 CXCL12 + CPYPP group were evaluated using paired *t*-test.

1159

1160 ***DOCK2* knockdown and IFN- α production assay in THP-1 Blue ISG cells**

1161 THP1-Blue ISG (InvivoGen) cells were cultured in 10% FBS, 2 mM L-glutamine, 25 mM
1162 HEPES. To generate lentivirus vectors, LentiCRISPR v2 expressing gRNA/Cas9⁵⁵, Gag-Pol
1163 packaging plasmid psPAX2 (Addgene #12260) and pMD2.G (Addgene #12259) were co-
1164 transfected to 293T cells using X-treme GENE 9 DNA Transfection Reagent (Roche). The
1165 guide RNA for *DOCK2* knock out and potential off-target effects evaluation^{56,57} were in
1166 **Supplementary Table 11**. Transfected 293T cells were cultured in Dulbecco's modified
1167 Eagle medium with 10% FBS and 50 units/ml penicillin/streptomycin. The cultured medium
1168 was replaced 12 hr after transfection. The virus containing supernatants were collected after
1169 a further 36 hr and filtered through a 0.45- μ m pore-size cellulose acetate filter (Sigma-Aldrich).
1170 Then, 2×10^6 THP1-Blue ISG cells were cultured in 2 ml polybrene (8 μ g/ml, Millipore)/virus-
1171 containing medium. After a 24 hr incubation, infected THP1-Blue ISG cells with virus
1172 containing medium were collected, centrifuged (400g, 4 min) and cultured in fresh medium.
1173 For selection LentiCRISPR vector expressing cells, infected cells were cultured for 4 days in
1174 medium supplemented with 1 μ g/ml puromycin 2 days after infection. *DOCK2* knock down
1175 efficiency was evaluated through quantitative real-time PCR analysis and western blotting
1176 (Abcam#ab124848). THP-1 monocytes are differentiated by 72 h incubation with 20 ng/mL
1177 phorbol 12-myristate 13-acetate (PMA, Sigma, P8139). IFN- α was evaluated 6 hr after
1178 stimulation (3 μ g/ml CpG-A ODN [D35, Gene Design] or control ODN [D35, GC]) using
1179 VeriKine-HS Human Interferon Alpha All Subtype TCM ELISA Kit (PBL).

1180

1181 **Immunohistochemical analysis of lung samples of COVID-19 pneumonia patients**

1182 The patient's samples of lung and hilar lymph node were obtained from autopsied cadaver
1183 died from COVID-19 pneumonia (Sample 1, 2, 3) and non-COVID-19 pneumonia (Sample 4,
1184 5). For staining control sample, lung and lymph node tissue section were obtained from the
1185 surgically resected lung specimens due to lung cancer. Immunohistochemistry for *DOCK2*
1186 was performed according to standard procedures. Briefly, formalin fixed paraffin embedded
1187 tissue sections of 5 mm were deparaffinized. Antigen retrieval was carried out using pressure
1188 cooking (in citrate buffer for 3 min). Endogenous peroxidase activity was blocked by
1189 incubating sections in 3% hydrogen peroxide for 5 min. After blocking, tissue sections were
1190 incubated with the anti-*DOCK2* rabbit polyclonal antibody⁵⁸ diluted in 1:1000. The EnVision
1191 kit from Dako (Glostrup, Denmark) was used to detect the staining.

1192

1193 ***In vivo* suppression of DOCK2 in Syrian hamster model with SARS-CoV-2 infection**

1194 **Virus:** SARS-CoV-2 (JPN/Kanagawa/KUH003)³³, was used in experimental animal model of
1195 COVID-19. An aliquot of virus was stored at -80°C until use.

1196 **Materials:** CPYPP, as DOCK2-Rac1 interaction inhibitor²⁹, was obtained from Tocris
1197 Bioscience (Bristol, UK). CPYPP was dissolved in the dimethyl sulfoxide (DMSO).

1198 **Animal experiments:** All applicable national and institutional guidelines for the care and use
1199 of animals were followed. The animal experimentation protocol was approved by the
1200 President of Kitasato University through the judgment of the Institutional Animal Care and
1201 Use Committee of Kitasato University (approval no. 21-007). Sample sizes were determined
1202 based on our experience with SARS-CoV-2 infection models, and the minimum number of
1203 animals was used.

1204

1205 **DOCK2 inhibition in Syrian hamster model of SARS-CoV-2 infection**

1206 We planned and executed the experimental schedule shown in **Extended Data Fig. 10a**. Six-
1207 week-old male Syrian hamsters (CLEA Japan, Inc. Tokyo, Japan) were maintained in the
1208 biological safety level 3 experimental animal facility of the Department of Veterinary Medicine,
1209 Kitasato University. Sixty-three animals were divided four groups: SARS-CoV-2+CPYPP (*n*
1210 = 29); SARS-CoV-2+vehicle (*n* = 28); mock+CPYPP (*n* = 3); and mock+vehicle (*n* = 3).
1211 Animals were intranasally inoculated with 10^{5.8} TCID₅₀ of SARS-CoV-2 or medium only (mock
1212 infection) at a volume of 100 µL, respectively. After 5 min (dpi 0) and 24 hr (dpi 1), animals
1213 were intraperitoneally injected with CPYPP (8.4 mg/head; 0.2 mL) or DMSO (vehicle; 0.2 mL).
1214 All animals were weighed daily. SARS-CoV-2 infected animals were euthanized on dpi 3, 6
1215 and 11 (8 animals per group on dpi 3 and dpi 6, and 6 animals per group on dpi 11), and then
1216 nasal swabs and tissues were collected. Lungs were dissected out from thoracic organs after
1217 euthanasia, and lung weights were measured at dpi 0, 3, 6 and 11. Differences of body weight
1218 and lung weight between SARS-CoV-2+CPYPP group and SARS-CoV-2+vehicle group were
1219 evaluated using two-sided Welch's *t*-test. Animals were euthanized when reaching the
1220 humane endpoint or 11 days after inoculation with SARS-CoV-2. The humane endpoint
1221 (weight loss of >25%) was based on the previous study³⁴.

1222 Syrian hamsters infected with CPYPP or vehicle were euthanized on dpi 3, 6, and 11
1223 for pathological examinations (*n* = 3). Histopathological examination of the lungs of the
1224 hamsters inoculated with SARS-CoV-2 with CPYPP or vehicle was conducted by hematoxylin
1225 and eosin staining. Pathological severity scores in the infected hamsters were evaluated as
1226 described elsewhere³⁴. Briefly, lung tissue sections were scored based on the percentage of

1227 inflammation area of the maximum cut surface collected from each animal in each group by
1228 using the following scoring system: 0, no pathological change; 1, affected area ($\leq 10\%$); 2,
1229 affected area ($< 50\%$, $> 10\%$); 3, affected area ($< 90\%$, $\geq 50\%$); 4, ($\geq 90\%$) an additional point
1230 was added when pulmonary edema and/or alveolar hemorrhage was observed. The total
1231 score is shown for individual animals. Immunohistochemistry for alveolar macrophage was
1232 performed according to standard procedures. Briefly, FFPE lung tissue section of infected
1233 Syrian hamster were incubated with the anti-CD68 mouse polyclonal antibody diluted in 1:400
1234 (Abcam#ab125212). The EnVision kit from Dako (Glostrup, Denmark) was used to detect the
1235 staining.

1236 Total RNA of nasal swab was extracted using QIAamp Viral RNA Mini kit (Qiagen,
1237 USA) according to the manufacturer's instructions. Each organ was homogenized by adding
1238 RLT buffer of QIAamp Viral RNA Mini kit using a multi-bead shocker (Yasui Kikai, Japan).
1239 After centrifugation of 10% (w/v) tissue homogenate at 10,000 rpm for 10 min, RNA was
1240 extracted from the recovered supernatants using the kit described above. The nucleocapsid
1241 (N) gene of SARS-CoV-2 was detected using THUNDERBIRD Probe One-step qRT-PCR
1242 (TOYOBO, Japan) and Primer/Probe N2 2019-nCoV (TaKaRa, Japan). To quantify SARS-
1243 CoV-2 N gene copies, a standard curve was generated using Positive Control RNA Mix 2019-
1244 nCoV (TaKaRa, Japan). Lung cytokine expression profile (IFNs, *IL-6*, and chemokines) were
1245 evaluated with the modifications of Ferren et al⁵⁹. Briefly, 100 ng of RNA was converted to
1246 cDNA with the ReverTra Ace qPCR RT Master Mix (TOYOBO, Japan). qPCR was performed
1247 with the THUNDERBIRD Probe qPCR Mix (TOYOBO, Japan). The primers and probes used
1248 are listed in **Supplementary Table 12**. The reaction of all samples was performed in
1249 duplicates using QuantStudio 1 Real-Time PCR System (Thermo Fisher Scientific, USA), and
1250 the target mRNA expression levels were normalized with GAPDH as a reference gene.
1251 Relative expression levels (fold changes) of mRNA from infected animals compared to
1252 uninfected animals were calculated by $2^{-\Delta\Delta C_t}$ method using QuantStudio Design and Analysis
1253 Software (Thermo Fisher Scientific, USA). Differences of viral load and lung cytokine
1254 expression profile between the two groups were evaluated using two-sided Wilcoxon rank
1255 sum test.

1256

1257 **Statistics and Reproducibility**

1258 **Figures 2m** and **2n** are representative images of immunohistochemical analysis of DOCK2
1259 in COVID-19 pneumonia and control without COVID-19 or pneumonia. **Extended Data Fig.9**
1260 shows all of the autopsied cadaver or surgical specimen examined in this study. For

1261 immunohistochemical analysis, all experiments were performed at least three sections of lung
1262 and hilar lymph node in each sample, and the similar results were confirmed.

1263

1264 **Data Availability**

1265 GWAS summary statistics and processed count matrices with de-identified metadata of bulk
1266 RNA-seq are deposited at the National Bioscience Database Center (NBDC) Human
1267 Database with the accession code hum0343 without restriction
1268 (<https://humandbs.biosciencedbc.jp/en/hum0343-latest>). Processed count matrices with de-
1269 identified metadata and embeddings of scRNA-seq are also deposited in the form of a Seurat
1270 object at the NBDC with the accession code hum0197 without restriction
1271 (<https://humandbs.biosciencedbc.jp/en/hum0197-latest>). GWAS genotype data of the
1272 COVID-19 cases are available under controlled access at European Genome-Phenome
1273 Archive (EGA) with the accession code [EGAS00001006284](https://ega-archive.org/studies/EGAS00001006284). The GWAS summary statistics
1274 of COVID-19 HGI (release 5) is obtained from <https://www.covid19hg.org/results/r5/>. The
1275 reference for cell type annotation of PBMC in scRNA-seq (pbmc_multimodal.h5seurat) is
1276 obtained from https://satijalab.org/seurat/articles/multimodal_reference_mapping.html.

1277

1278 **Code Availability**

1279 We used publicly available software for the analyses. The software used is listed in the
1280 Methods section.

1336

1337 **Extended Data Fig. 1. Japan COVID-19 Task Force**

1338 Japan COVID-19 Task Force is a nation-wide consortium to overcome COVID-19 pandemic
1339 in Japan, which was established in early 2020. Japan COVID-19 Task Force consists of >100
1340 hospitals (red dots) led by core academic institutes (blue labels), and collected DNA, RNA,
1341 and plasma from the COVID-19 cases along with detailed clinical information. The figure was
1342 originally created using sf and ggplot2 R packages based on Global Map Japan version 2.1
1343 Vector data (Geospatial Information Authority of Japan).

1344

1345 **Extended Data Fig. 2. A principal component analysis plot of the GWAS participants**
1346 **and manhattan and quantile-quantile plots of the GWAS**

1347 **(a, b)** A principal component analysis (PCA) plot of the GWAS participants (COVID-19 cases
1348 and controls) along with and without International HapMap populations (**a** and **b**, respectively).
1349 **(c)** Manhattan plots and quantile-quantile plots of the Japanese GWAS of COVID-19.
1350 Uncorrected P values from GWAS analysis are shown. Dotted lines represent the genome-
1351 wide significance threshold of $P < 5.0 \times 10^{-8}$.

1352

1353 **Extended Data Fig. 3. Regional association plots of the HLA imputation analysis**

1354 Regional association plots of the HLA imputation analysis results. Dots represent SNPs and
1355 HLA variants with colors according to the legend. Uncorrected P values from HLA imputation
1356 analysis are shown. Dotted lines represent the genome-wide significance threshold of $P <$
1357 5.0×10^{-8} . HLA genes with the most significant associations in each of the case-control
1358 phenotypes are indicated.

1359

1360 **Extended Data Fig. 4. ABO blood type associations with COVID-19 in Japanese and**
1361 **cross-population Mendelian randomization analysis of the COVID-19 GWAS**

1362 **(a)** Odds ratios of the ABO blood types in the Japanese population are indicated. Dots
1363 represent the odds ratios and bars represent the 95 % confidence intervals. P values are
1364 uncorrected. Detailed results are presented in **Supplementary table 5**. **(b)** Forest plots of
1365 the Mendelian randomization (MR) analysis results of causal inference on the COVID-19
1366 GWAS in Japanese (left panel) and Europeans (right panel). Since effect sizes (= beta) of
1367 MR are not scalable among phenotypes and populations, normalized beta is indicated. For

1368 each phenotype and population, the standard error for the COVID-19 GWAS with the largest
1369 sample size (i.e., “COVID-19 vs control” for Japanese and “Self-reported COVID-19 vs
1370 control (C2)” for Europeans) was set to be 0.1. Dots represent the effect size normalized beta
1371 estimates and bars represent the 95 % confidence intervals. *P* values are uncorrected. The
1372 abbreviations of the exposure phenotypes and the detailed MR results are given in
1373 **Supplementary Table 6** and **Supplementary Table 7**. BMI; body mass index, T2D; type 2
1374 diabetes, CPD; cigarettes per day, CAD; cardiovascular disease, SBP; systolic blood
1375 pressure, DBP; diastolic blood pressure, eGFR; estimated glomerular filtration rate, UA;
1376 serum uric acids, RA; rheumatoid arthritis, SLE; systemic lupus erythematosus.

1377

1378 **Extended Data Fig. 5. Effect size comparisons of the COVID-19 risk loci between the**
1379 **discovery GWAS and the replication study**

1380 Co-plots of the odds ratios and 95% confidence intervals between the discovery GWAS
1381 cohort and replication cohort. To focus on the differences in the cases collected in different
1382 pandemic waves (initial waves for GWAS and latter waves for the replication), same controls
1383 as GWAS were currently used for the cases in the replication. A regression coefficient was
1384 estimated based on logarithm of odds ratios. Dots represent the odds ratios and bars
1385 represent the 95 % confidence intervals.

1386

1387 **Extended Data Fig. 6. Colocalization analysis of the GWAS and eQTL signals at the**
1388 ***DOCK2* locus**

1389 Regional colocalization plots of the GWAS signals (severe and younger COVID-19 cases vs
1390 controls) and the eQTL signals on *DOCK2* expression in the COVID-19 patients at the
1391 *DOCK2* locus. CLPP; colocalization posterior probability. The eQTL effects of the variants
1392 around *DOCK2* region are given in **Supplementary Table 10**.

1393

1394 **Extended Data Fig. 7. Cell type definition and gene ontology enrichment analysis of**
1395 ***DOCK2* co-expression gene module in the PBMC single cell analysis**

1396 (a) Violin plots showing the expression distribution of selected canonical cell markers in the
1397 12 clusters of PBMC. The rows represent selected marker genes and the columns represent
1398 clusters with the same color as in **Fig. 2d**. (b) Violin plots showing the expression distribution
1399 of selected canonical cell markers in the 5 clusters of innate immune cell clusters, shown in
1400 the same color as in **Fig. 2h**. (c) Tile plot showing percentage concordance between the

1401 manually annotated 12 clusters and Azimuth annotation. (d) The top 25 enriched biological
1402 processes by gene ontology (GO) analysis of *DOCK2* co-expression gene module identified
1403 by weighted gene co-expression network analysis (WGCNA) in the non-classical monocytes
1404 of COVID-19 patients, where *DOCK2* showed the highest cell type-specific expression profile.
1405 The color of the dots represents the adjusted *P* values.

1406

1407 **Extended Data Fig. 8. Biological impacts of *DOCK2* downregulation in primary cells**
1408 **and *DOCK2* knockdown and Interferon- α production assay in THP-1 Blue ISG cells**

1409 (a) The impact of *DOCK2* downregulation on interferon- α (*IFN- α*) production ability in pDC.
1410 Sorted pDC were stimulated with CpG and/or CPYPP. Data shows means \pm s.e.m. ($n = 3$ per
1411 group). Differences of *IFN- α* production ability between the groups were evaluated using two-
1412 sided paired *t*-test. (b) The impact of *DOCK2* downregulation on chemotaxis in CD3⁺ T cells.
1413 CD3⁺ T cells were stimulated with CXCL12 or CXCL12 + CPYPP ($n = 19$ per group).
1414 Differences of chemotaxis between the groups were evaluated using two-sided paired *t*-test.
1415 (c, d) Knockdown of *DOCK2* by CRISPR system was confirmed by western blotting (c) and
1416 qRT-PCR. (d) Semi-quantitative staining density measure was determined using ImageJ
1417 (NIH). Data shows means \pm s.e.m. ($n = 3$ per group). Data are compared to control group. *P*
1418 values were determined with One-way ANOVA followed by Dunnett's post hoc test. (e, f)
1419 Activity ratio of SEAP reporter to no treatment group. Reporter was activated by 50 ng/ml
1420 LPS (e) or 50 μ g/ml polyIC (f). Data shows means \pm s.e.m. ($n = 3$ per group). Data are
1421 compared to control group. *P* values were determined with One-way ANOVA followed by
1422 Dunnett's post hoc test.

1423

1424 **Extended Data Fig. 9. Immunohistochemical analysis for *DOCK2***

1425 Lung and hilar lymph nodes were obtained from autopsied cadaver (Sample 1-3, 6, 7) or
1426 surgical specimen (Sample 4, 5), and stained by anti-*DOCK2* polyclonal antibody. Sample 1-
1427 3; COVID-19 pneumonia. Sample 4-5; control. Sample 6; non-COVID-19 severe pneumonia.
1428 Sample 7; non-COVID-19 mild pneumonia.

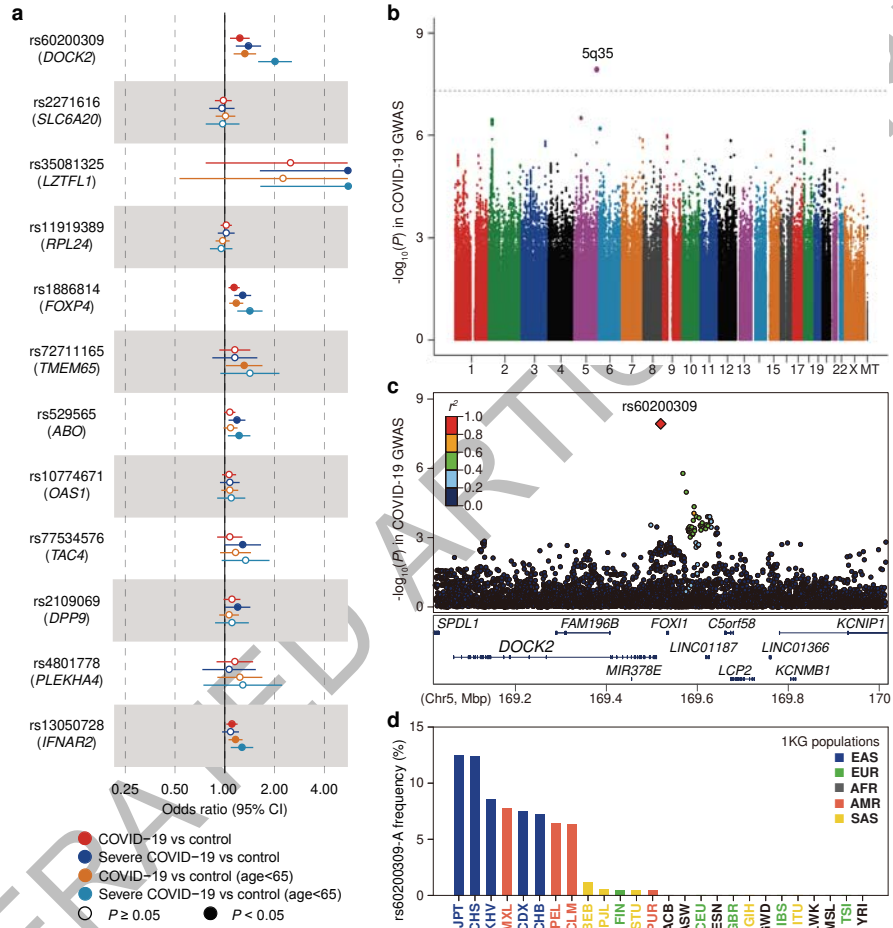

1429

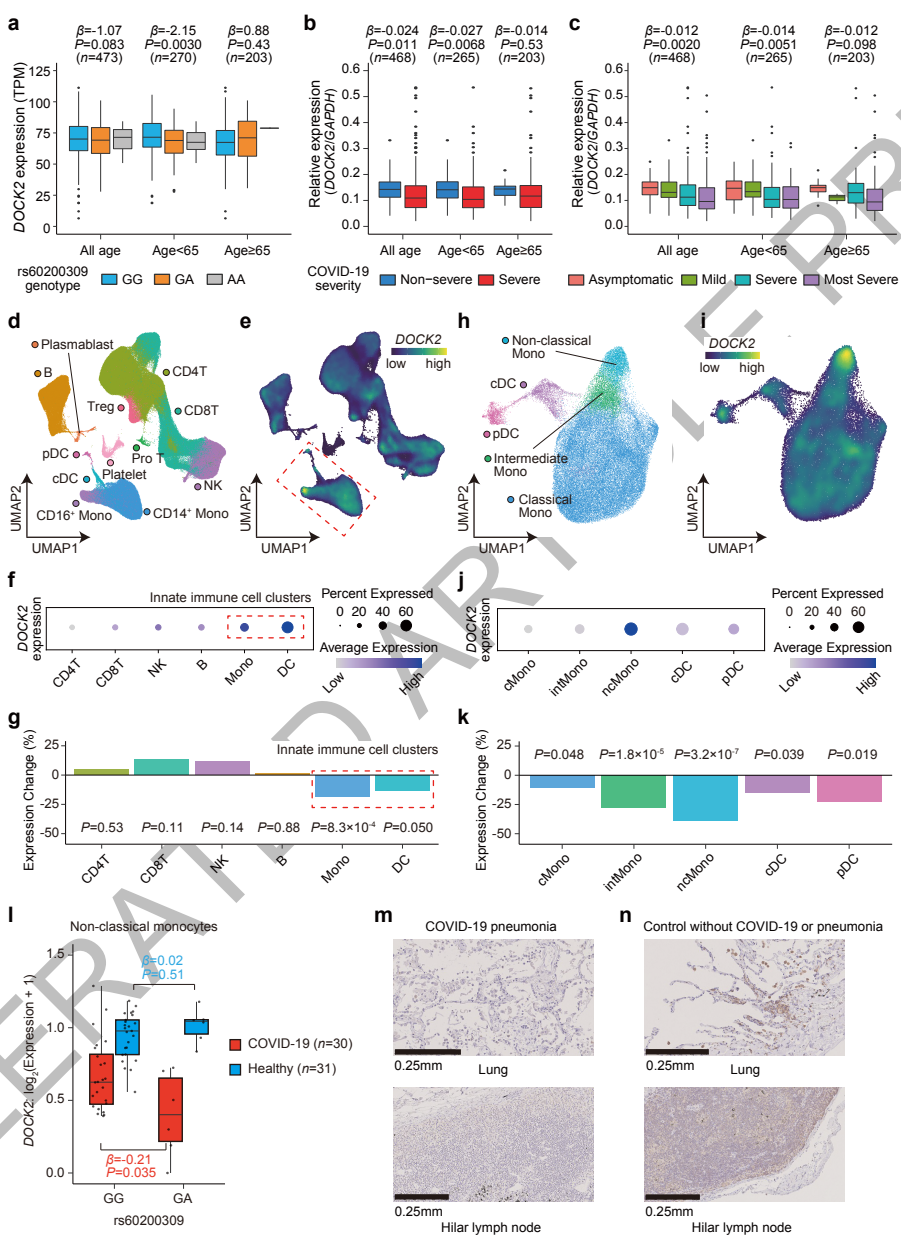

1430 **Extended Data Fig. 10. *In vivo* suppression of *DOCK2* in a Syrian hamster model with**
1431 **SARS-CoV-2 infection**

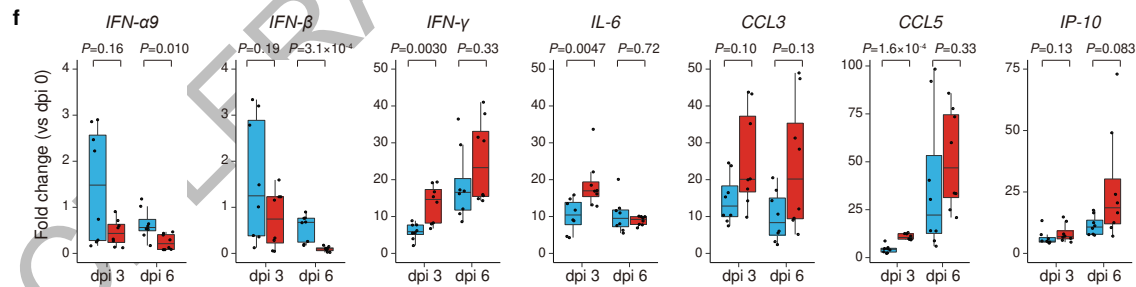

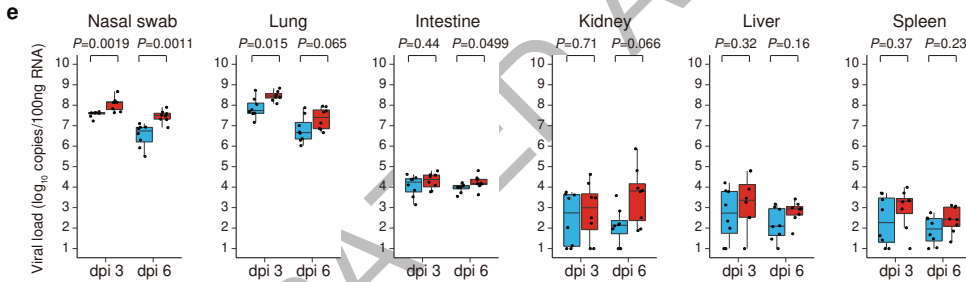

1432 (a) Schematic timeline of the experimental procedure. (b) Changes in weight of uninfected
1433 animals. The error bars represent standard error of the mean. (c) Changes in weight of each

1434 of the infected animals, corresponding to **Fig 3a**. Three CPYPP-administrated animals
1435 reaching humane endpoint were euthanized at dpi 7 and 9, lowering survival rate to 77%
1436 (=10/13), while survival of vehicle-administrated animals was 100% (=12/12). The animals
1437 were administered with CPYPP (red), or vehicle (blue). **(d)** Histopathological examination of
1438 the lungs of infected hamsters. Syrian hamsters were inoculated with SARS-CoV-2 with
1439 CPYPP or Vehicle. Syrian hamsters infected with CPYPP or Vehicle were euthanized on dpi
1440 3, 6, and 11 for pathological examinations ($n = 3$). Shown are pathological findings in the
1441 lungs of hamsters infected with the virus on dpi 3, 6, and 11 (hematoxylin and eosin staining).
1442 Middle and Right show enlarged views of the area circled in black in Left. (Scale bars, 2.5
1443 mm [Left], 1.0 mm [Middle], and 0.25 mm [Right].) **(e)** Immunohistochemistry for alveolar
1444 macrophages. Shown are immunohistochemical findings in the lungs of hamsters infected
1445 with the virus on dpi 6 ($n = 3$ per group). Lung tissue was stained with the anti-CD68 mouse
1446 monoclonal antibody. (Scale bars, 0.25 mm.) **(f)** Pathological severity scores in infected
1447 hamsters. To evaluate comprehensive histological changes, lung tissue sections were scored
1448 based on **(d)** pathological changes. Scores were determined based on the percentage of
1449 inflammation area of the maximum cut surface collected from each animal in each group by
1450 using the following scoring system: 0, no pathological change; 1, affected area ($\leq 10\%$); 2,
1451 affected area ($< 50\%$, $> 10\%$); 3, affected area ($< 90\%$, $\geq 50\%$); 4, ($\geq 90\%$) an additional point
1452 was added when pulmonary edema and/or alveolar hemorrhage was observed. The total
1453 score is shown for individual animals. Blue dot and red dot indicate +Vehicle and +CPYPP,
1454 respectively.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our [Editorial Policies](#) and the [Editorial Policy Checklist](#).

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a Confirmed

- The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement
- A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
- The statistical test(s) used AND whether they are one- or two-sided
Only common tests should be described solely by name; describe more complex techniques in the Methods section.
- A description of all covariates tested
- A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
- A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
- For null hypothesis testing, the test statistic (e.g. F , t , r) with confidence intervals, effect sizes, degrees of freedom and P value noted
Give P values as exact values whenever suitable.
- For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
- For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
- Estimates of effect sizes (e.g. Cohen's d , Pearson's r), indicating how they were calculated

Our web collection on [statistics for biologists](#) contains articles on many of the points above.

Software and code

Policy information about [availability of computer code](#)

Data collection

Data analysis

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio [guidelines for submitting code & software](#) for further information.

Data

Policy information about [availability of data](#)

All manuscripts must include a [data availability statement](#). This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our [policy](#)

GWAS summary statistics and processed count matrices of bulk RNA-seq are deposited at the National Bioscience Database Center (NBDC) Human Database with the accession code hum0343 without restriction (<https://humandbs.biosciencedbc.jp/en/hum0343-latest>). Raw sequencing data of scRNA-seq are available under controlled access at the Japanese Genotype-phenotype Archive (JGA) with accession codes JGAS000543/JGAD000662 for general research use (<https://ddbj.nig.ac.jp/resource/jga-study/JGAS000543>), which can be accessed through application at the NBDC with the accession code hum0197 (<https://humandbs.biosciencedbc.jp/en/hum0197-latest>). GWAS genotype data of the COVID-19 cases are available under controlled access at European Genome-Phenome

Archive (EGA) with the accession code EGAS00001006284 for general research use (<https://ega-archive.org/studies/EGAS00001006284>). GWAS genotype data of the controls collected at Osaka University and the affiliated medical institutes (n=2,380) are available under controlled access at EGA with the accession code EGAS00001006423 for the use as the controls (<https://ega-archive.org/studies/EGAS00001006423>). GWAS genotype data of the controls collected at University of Tsukuba (n=909) cannot be deposited since no consent was obtained for deposition in a public repository, but these data are available upon request (contact: Prof. Nobuyuki Hizawa; nhizawa@md.tsukuba.ac.jp) for the use as controls in research of inflammatory lung diseases.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

Life sciences Behavioural & social sciences Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see nature.com/documents/nr-reporting-summary-flat.pdf

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size	We recruited 2,520 COVID-19 cases who required hospitalization from April 2020 to January 2021 (the 1st to 3rd pandemic waves in Japan) from >100 hospitals participating in Japan COVID-19 Task Force. 3,341 control subjects were collected as general Japanese populations at Osaka University and affiliated institutes. All sample size in GWASs in this study is summarized in Table 1, Supplementary Table2 and 8. Among COVID-19 cases, we enrolled 475 cases for bulk RNA-seq analysis and qPCR-based DE analysis. All sample size in bulk RNA-seq analysis in this study is summarized in Supplementary Table2. We recruited 30 severe COVID-19 cases and 31 healthy controls for PBMC scRNA-seq analysis. We recruited 19 healthy controls for evaluation of biological impacts of DOCK2 downregulation using primary cells. We obtained the samples of lung and hilar lymph node from autopsied cadaver died from COVID-19 pneumonia (N=3), non-COVID-19 pneumonia (N=2) and lung and lymph node tissue section surgically resected due to lung cancer for control sample (N=2).
Data exclusions	We excluded samples with low genotyping call rate, samples in close genetic relation, and ancestry outliers of East Asian population in GWAS analysis. We excluded PCA outliers of gene expression in bulk RNA-seq analysis.
Replication	We enrolled 1,243 severe COVID-19 cases collected from February 2021 to September 2021 (the 4th to 5th pandemic waves in Japan) through Japan COVID-19 Task Force and 3,769 controls as general Japanese populations at Osaka University Graduate School of Medicine, affiliated institutes and the Biobank Japan Project. We replicated an age-specific nominal risk of the DOCK2 variant (rs60200309) in the younger COVID-19 cases (OR=1.28, 95%CI=1.02-1.61, P=0.033). We also obtained the association of the rs60200309 from the pan-ancestry meta-analysis available at https://rgc-covid19.regeneron.com/ . We observed the same directional effect with a marginal association signal (OR=1.73, 95%CI=0.95-3.15, P=0.072).
Randomization	We did not need to use randomization in this study because this is a genotype-phenotype association study. All the samples with available accessibility to genotype and phenotype data were included in the analysis.
Blinding	We did not apply blinding of the samples because this is a genotype-phenotype association study and no intervention was conducted in our study.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Antibodies

Antibodies used

Anti-DOCK2 rabbit polyclonal antibody was originally raised using affinity-purified DOCK2 c-terminus antigen in a previous study (Biochim Biophys Acta. 1999; 1452:179-187).
anti-DOCK2; Abcam#ab124838
anti-b-actin; Sigma#A5441
anti-CD68; Abcam#ab12512

Validation

Anti-DOCK2 rabbit polyclonal antibody was validated for IHC and western blotting (Blood .2002;100(12):3968-74., Biochem Biophys Res Commun. 2010 Apr 23;395(1):111-5.).
 Anti-DOCK2 antibody is validated for WB and IHC (Abcam).
 Anti-β-actin antibody is validated for WB and IF (Sigma).
 Anti-CD68 antibody is validated for IHC (Abcam).

Eukaryotic cell lines

Policy information about [cell lines](#)

Cell line source(s)	THP1-Blue ISG cells (human THP-1 monocyte cell line by stable integration of an interferon regulatory factor (IRF)-inducible SEAP reporter construct)
Authentication	None, but used for experiments within two months after obtaining from the vendor, Invivogen.
Mycoplasma contamination	No mycoplasma
Commonly misidentified lines (See ICLAC register)	None.

Animals and other organisms

Policy information about [studies involving animals](#); [ARRIVE guidelines](#) recommended for reporting animal research

Laboratory animals	Syrian hamsters were purchased from CLEA Japan, Inc. Tokyo, Japan. Six-week-old male Syrian hamsters were maintained in the biological safety level 3 experimental animal facility of the Department of Veterinary Medicine, Kitasato University. Animals were cared for according to the Guidelines for Animal Experiments of Kitasato University and the National Institutes of Health Guide for the Care and Use of Laboratory Animals.
Wild animals	Not used in this study.
Field-collected samples	Not used in this study.
Ethics oversight	The animal experimentation protocol was approved by the President of Kitasato University through the judgment of the Institutional Animal Care and Use Committee of Kitasato University (approval no. 21-007).

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Human research participants

Policy information about [studies involving human research participants](#)

Population characteristics	COVID-19 cases in the GWAS are of East Asian ancestry, the mean age was 56, 64% were male, and all of them were tested positive for PCR test results. Controls in the GWAS are of East Asian ancestry, the mean age was 53, 48% were male. Mean age of COVID-19 cases in the bulk RNA-seq analysis was 60, 68% were male. Details of the characteristics of the study participants in the GWAS, bulk RNA-seq analysis and replication analysis are summarized in Supplementary Table2.
Recruitment	We enrolled the hospitalized cases diagnosed as COVID-19 by physicians using the clinical manifestation and PCR test results, who were recruited from April 2020 to January 2021 (the 1st to 3rd pandemic waves in Japan) at any of the >100 the affiliated hospitals participating to Japan COVID-19 Task Force. All control participants in GWAS were recruited at Osaka University or related institutions. We incorporated 475 COVID-19 cases collected at the core medical institutes of Japan COVID-19 Task Force and included in the GWAS for bulk RNA-seq analysis and qPCR-based DE analysis. We enrolled severe COVID-19 cases and healthy controls for PBMC scRNA-seq analysis at Osaka University. We recruited healthy controls for evaluation of biological impacts of DOCK2 downregulation using primary cells at Osaka University. We obtained the samples of lung and hilar lymph node from autopsied cadaver died from COVID-19 pneumonia, non-COVID-19 pneumonia and lung and lymph node tissue section surgically resected due to lung cancer for control sample through Japan COVID-19 Task Force.
Ethics oversight	This study was approved by the ethical committees of Keio University School of Medicine, Osaka University Graduate School of Medicine, and affiliated institutes.

Note that full information on the approval of the study protocol must also be provided in the manuscript.
