The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic has dramatically expedited global vaccine development efforts^{1–3}, most targeting the viral ‘spike’ glycoprotein (S). S localizes on the virion surface and mediates recognition of cellular receptor angiotensin-converting enzyme 2 (ACE2)^{4–6}. Eliciting neutralizing antibodies that block S-ACE2 interaction^{7–9}, or indirectly prevent membrane fusion¹⁰, constitute an attractive modality for vaccine-elicited protection¹¹. However, although prototypic S-based vaccines show promise in animal models^{12–14}, the immunogenic properties of S in humans are poorly resolved. In this study, we characterized humoral and circulating follicular helper T cell (cTFH) immunity against spike in recovered patients with coronavirus disease 2019 (COVID-19). We found that S-specific antibodies, memory B cells and cTFH are consistently elicited after SARS-CoV-2 infection, demarking robust humoral immunity and positively associated with plasma neutralizing activity. Comparatively low frequencies of B cells or cTFH specific for the receptor binding domain of S were elicited. Notably, the phenotype of S-specific cTFH differentiated subjects with potent neutralizing responses, providing a potential biomarker of potency for S-based vaccines entering the clinic. Overall, although patients who recovered from COVID-19 displayed multiple hallmarks of effective immune recognition of S, the wide spectrum of neutralizing activity observed suggests that vaccines might require strategies to selectively target the most potent neutralizing epitopes.

Plasma and peripheral blood mononuclear cells (PBMCs) were collected from a cross-sectional cohort ($n=41$) of Australian adults who recovered from mild-to-moderate SARS-CoV-2 infection a median of 32 d (interquartile range (IQR), 28–35 d) after positive PCR test. Demographic and clinical characteristics of patients with COVID-19, and a control cohort of 27 adults recruited before widespread infection in Australia, are reported in Extended Data Fig. 1. To examine the degree to which baseline cross-reactive coronavirus immunity affected SARS-CoV-2 responses, we pre-screened uninfected individuals for antibodies against the spike protein of beta

coronavirus HCoV-HKU1 (HKU1) (Extended Data Fig. 2), selecting individuals with the five highest and five lowest plasma titers as controls for the study.

Serological profiles are presented stratified across the cohort based on neutralization activity for each individual. ELISAs were performed using recombinant trimeric S incorporating furin cleavage site removal and stabilizing proline substitutions, or the monomeric receptor-binding domain (RBD) subunit (residues 319–541). Antibodies binding S (Fig. 1a; median endpoint titer, 2,557; IQR, 1,298–7,098) or RBD (Fig. 1b; median, 1,332; IQR, 626–3,445) were observed in all participants with COVID-19 and were highly correlated (Extended Data Fig. 3), with minimal reactivity in controls. Consistent with previous reports¹⁵, minimal antibody cross-recognition of the SARS-CoV RBD was observed (Fig. 1c; median, 383; IQR, 226–763). Antibody responses to HKU1 were widely prevalent with endpoint titers generally greater than SARS-CoV-2 titers (Fig. 1d; median, 4,897; IQR, 2,377–8,562), in line with widespread seropositivity to human coronaviruses reported in adults^{16,17}. The capacity of immune plasma to block interaction between recombinant ACE2 and RBD was assessed by ELISA (Methods), with modest inhibition (median, 14.1%; IQR, 10.1–19.3) detected in most subjects, and only 3 of 41 subjects exhibiting more than 50% inhibition activity (Fig. 1e). Although the modest overall signal intensity of this assay might reflect occlusion of some RBD epitopes by plate binding, inhibition activity did track with neutralizing activity ($r=0.53$; Extended Data Fig. 3), suggesting that, in most subjects, antibody blockade of ACE2 recognition contributes to neutralization activity. Virus-neutralizing activity in plasma was assessed using a microneutralization assay with live SARS-CoV-2 infection of Vero cells (Methods), as previously described for SARS-CoV and MERS-CoV^{18,19}. Neutralizing antibody titers were generally modest (Fig. 1f; median plasma dilution, 202; IQR, 113–254), consistent with other reports in convalescent cohorts²⁰. S- and RBD-specific antibody responses were consistently elicited by SARS-CoV-2 infection, with serological endpoint titers correlating significantly with neutralizing activity ($r=0.55$ and $r=0.61$, respectively) and ACE2–RBD binding inhibition ($r=0.72$ and $r=0.72$, respectively) in the plasma (Extended Data Fig. 3).

Fig. 1 | Serological responses to COVID-19. a–d, Plasma samples from patients who recovered from SARS-CoV-2 infection ($n=41$) and healthy controls ($n=10$, black/gray bars) were screened by ELISA for reactivity against S recombinant proteins from SARS-CoV-2 S (**a**), SARS-CoV-2 RBD (**b**), SARS-CoV RBD (**c**) and HCoV-HKU1 (**d**). **e**, The capacity of plasma antibodies to inhibit the interaction of RBD with human ACE2 was tested in an ELISA format at a plasma dilution of 1:25. **f**, Neutralization activity in the plasma was assessed using a microneutralization assay. Data represent individual responses for each individual, and column order for all figures is conserved and stratified on the basis of plasma neutralization activity. SARS-CoV-2-negative donors were stratified based on HKU1 serological titers (black, high titers; gray, low titers).

The frequency and specificity of class-switched ($CD19^+IgD^-$) B cells was examined using S or RBD flow cytometric probes (Methods; gating in Supplementary Fig. 1). In contrast to uninfected

controls, clear populations of B cells binding spike (S^+RBD^-), spike and RBD (S^+RBD^+) or RBD alone (S^-RBD^+) could be resolved in recovered COVID-19 patients (Fig. 2a and Extended Data Fig. 4) and comprised a respective 0.38% (IQR, 0.24–0.52), 0.047% (IQR, 0.023–0.084) and 0.033% (IQR, 0.015–0.045) of the $CD19^+IgD^-$ population (Fig. 2b). The very low frequencies of S^-RBD^+ B cells were likely a mix of background staining and binding to RBD epitopes usually occluded in S. Immunoglobulin isotypes were determined by IgM and IgG surface staining, with IgM–IgG⁺ class-switched B cells previously established as almost exclusively IgA^+ (ref. ²¹). Most S^+RBD^- B cells were IgG^+ (median, 57.5%; IQR, 46.8–64.8), with smaller proportions of IgM^+ (20.9%; IQR, 17.4–29.1) and IgA^+ ($IgM-IgG^-$, 17.4%; IQR, 13.2–25.9; Fig. 2c). Isotype distribution of S^+RBD^+ B cells was variable due to low event counts, with median frequencies of 45.5% IgG (IQR, 27.8–70.7), 13.6% IgM (IQR, 0–30.3) and 20.0% IgA (IQR, 4.73–41.9). The activation phenotype of antigen-specific B cells was assessed using CD21 and CD27 (ref. ²²) (Extended Data Fig. 5), with S^+RBD^- (median, 58.5%; IQR, 52.2–66.6) or S^+RBD^+ (median, 68.7%; IQR, 54.4–80) B cells predominantly exhibiting a resting memory phenotype ($CD21^+CD27^+$), consistent with the median time since infection. However, notable proportions of activated memory B cells ($CD21^-CD27^+$) were still evident for both S^+RBD^- (18.9%; IQR, 13.2–25.7) or S^+RBD^+ populations (13.2%; IQR, 5.88–20), with minimal $CD21^-CD27^-$ and $CD21^+CD27^-$ phenotypes observed.

The RBD of SARS-CoV and SARS-CoV-2 share significant homology but with marked diversity within the ACE2 binding motif^{4,23}. To better understand individuals with notable RBD-specific antibody titers but limited neutralization or RBD–ACE2 inhibition, we tested differential staining with SARS-CoV and SARS-CoV-2 RBD probes to more precisely quantify B cells recognizing the unique ACE2 binding site of SARS-CoV-2. Cells from a subset of COVID-19 convalescent subjects ($n=15$), selected across a range of serum neutralization activities but with prominent RBD-specific B cell populations, were stained as before with S, RBD and SARS-CoV RBD probes (Fig. 2d). Both SARS-CoV-2 RBD-specific and SARS-CoV/SARS-CoV-2 RBD cross-reactive IgG^+ B cell populations could be resolved (gating in Supplementary Fig. 2), with the former comprising the major fraction of the S^+RBD^+ response (Fig. 2e). However, although increased proportions of B cells uniquely binding SARS-CoV-2 RBD does broadly track with plasma blockade of RBD–ACE2 binding (Fig. 2f; $r=0.46$), we found no correlation with neutralization activity (Fig. 2g; $r=0.05$).

To better understand the immunoglobulins expressed by S- or RBD-specific B cells, we sorted probe⁺ IgG^+ B cells from five subjects with high plasma neutralizing titers. A total of 612 (512 S-specific and 100 RBD-specific) productive recombinant heavy chain sequences were recovered, 98 (16%) from clonally expanded families, with 302 κ and 89 λ light chain pairs. IGHV, IGKV and IGLV gene use was diverse, with a normal human distribution of CDR-H3 lengths (Extended Data Fig. 6). IGHV somatic mutation of S- and RBD-specific immunoglobulins was similar between subjects, with a median of 1.7% (IQR, 1.0–2.8) and 2.0% (IQR, 1.1–3.4), respectively, in line with other primary infections^{24,25} but lower than influenza B HA-specific B cells after immunization (6.25%)²⁶ or chronic infections²⁷.

TFH cells provide critical cognate help to antigen-specific B cells to initiate and maintain humoral immune responses²⁸. cTFH cells ($CD3^+CD4^+CD45RA^-CXCR5^+$, gating in Supplementary Fig. 3) in the blood constitute a surrogate of TFH activity in lymphoid tissues^{29,30}. Total unstimulated cTFH frequencies were similar across SARS-CoV-2 convalescent and uninfected donors (Extended Data Fig. 7a). Antigen specificity of the cTFH population was determined using an activation induced marker assay³¹ after stimulation with S or RBD proteins (Fig. 3a) or overlapping peptide pools (Methods and Extended Data Fig. 7b). Recovered patients exhibited robust

Fig. 2 | Frequency and phenotype of SARS-CoV-2-specific B cells after infection. **a**, Co-staining class-switched B cells (CD19⁺IgD⁻) with SARS-CoV-2 spike and RBD probes allows resolution of antigen-specific cells in individuals previously infected with SARS-CoV-2 relative to uninfected controls. **b**, Frequencies of spike⁺RBD⁻, spike⁺RBD⁺ and spike⁻RBD⁺ B cells as a proportion of CD19⁺IgD⁻ B cells in PBMCs from patients previously infected with SARS-CoV-2 ($n = 41$) and uninfected controls ($n = 10$). **c**, Isotype distribution of spike⁺RBD⁻ and spike⁺RBD⁺ CD19⁺IgD⁻ B cells; ND, not detected due to absent probe⁺ cells ($n = 41$). **d**, Co-staining spike⁺CD19⁺IgD⁻ B cells with SARS-CoV-2 and SARS-CoV RBD probes allows discrimination of cross-reactive specificities versus those unique to SARS-CoV-2. **e–g**, Frequency of SARS-CoV-2 RBD⁺/SARS-CoV RBD⁻ cells as a proportion of spike⁺CD19⁺IgD⁻IgG⁺ B cells ($n = 15$) (**e**) and their correlation (Spearman's, two-tailed) to ACE2-RBD binding inhibition (**f**) and neutralizing activity in plasma (**g**). **b**, **e**, Data are shown as the median with IQR.

Fig. 3 | Specificity of cTFH responses to coronavirus spike proteins. a, Representative staining of CD25 and CD134 co-expression on cTFH (CD3⁺CD4⁺CD45RA⁻CXCR5⁺) cells after stimulation with 5 $\mu\text{g ml}^{-1}$ BSA (negative control), SARS-CoV-2 S, SARS-CoV-2 RBD or HKU1 spike protein or SEB (positive control). **b**, Antigen-specific cTFH ($n=10$ SARS-CoV-2⁻ donors, $n=41$ SARS-CoV-2⁺ donors) frequencies were calculated as the proportion of CD25⁺CD134⁺ cTFH cells in each stimulation condition after background subtraction using the negative control. **c**, Representative expression of CCR6 and CXCR3 on bulk cTFH, SARS-CoV-2 spike-specific, HKU1 spike-specific or SEB-responsive (CD25⁺OX-40⁺) cTFH. **d**, Quantification of CCR6⁺CXCR3⁻, CCR6⁺CXCR3⁺, CCR6⁻CXCR3⁺ or CCR6⁻CXCR3⁻ cTFH populations among SARS-CoV-2⁺ donors ($n=41$). **b,d**, Data are shown as the median with IQR.

cTFH responses to S (median, 0.92% S-specific, cTFH; IQR, 0.42–1.52), whereas RBD-specific cTFH (median, 0.12%; IQR, 0.04–0.38) was significantly less frequent ($P<0.0001$) (Fig. 3b). Consistent with high HKU1 seropositivity (Fig. 1d), cTFH responses to HKU1 spike were detected in 97.5% of donors (median, 0.52% of cTFH cells; IQR, 0.32–0.99), with higher frequencies generally observed within COVID-19 convalescent donors than uninfected controls (Fig. 3b), suggestive of boosting of cross-reactive T cells by SARS-CoV-2 infection.

cTFH cells have classically been divided using surface expression of chemokine receptors CCR6 and CXCR3 (refs. ^{30,32,33}). However, the functional capacities of putative cTFH1 (CCR6⁺CXCR3⁺), cTFH2 (CCR6⁺CXCR3⁻) and TH17-like cTFH (CCR6⁺CXCR3⁻) subsets are still unclear and might vary with anatomical or pathogenic context^{29,30,33}. S-specific (median, 52.6%) or HKU1 spike-specific (median, 62.9%) cTFH cells were significantly enriched for CCR6⁺CXCR3⁻ cells ($P<0.0001$; Fig. 3c,d) compared to the unstimulated total cTFH population (median, 21.1%) or SEB

Fig. 4 | Predictors of plasma neutralization activity. **a**, Co-correlation matrix of characteristics, infection and immunological dynamics in patients who recovered from SARS-CoV-2 infection. Correlations (Spearman's, two-tailed) that did not reach significance of $P < 0.05$ were not displayed in the matrix. **b**, PCA of immune parameters showing individuals colored in proportion to plasma neutralization titers. **c**, Spearman's correlation (two-tailed) of the plasma neutralization activity with S-specific antibody titers and the proportion of CCR6+CXCR3- cells within the S-specific cTFH population ($n = 41$).

stimulated controls. Although TFH³¹ and cTFH are poor cytokine producers relative to conventional CD4 memory (Tmem) cells (CD3⁺CD4⁺CD45RA⁻CXCR5⁻) (Extended Data Fig. 7c), CCR6⁺ and CXCR3⁺ cTFH exhibited Th17 and Th1-like cytokine profiles, respectively (Extended Data Fig. 7d). We identified an immunogenic peptide derived from S2, LLQYGSFCTQLNRAL, which elicited cTFH responses in three donors (Extended Data Fig. 8a). In each case, the CCR6/CXCR3 phenotype of peptide-specific cTFH was similar to the phenotype of the bulk S2-responding cells (Extended Data Fig. 8b).

Tmem responses were similar to cTFH—namely, strong reactivity to S and HKU1 spike proteins (median, 0.53% and 0.54% of CD4 memory cells, respectively) and lower frequencies of RBD-specific T cells (median, 0.24% of CD4 memory cells) (Extended Data Fig. 9a,b). Consistent with other reports^{34,35}, S-specific Tmem produced interferon (IFN)- γ and tumor necrosis factor (TNF) in response to both S1 and S2 peptide pools, with interleukin (IL)-17 responses approximately ten-fold lower in magnitude (Extended Data Fig. 9c).

Serological neutralization activity will be a critical endpoint for upcoming SARS-CoV-2 vaccine trials. A co-correlation matrix of subject characteristics and immunological parameters highlighted broad co-correlation of immune parameters related to S immunogenicity, including plasma antibody titers and frequencies of S-specific B and cTFH cell populations (Fig. 4a). Notably, neutralization activity positively correlated with S and RBD antibody titers, S- and RBD-specific B cell frequencies and S-specific cTFH (including CCR6⁺CXCR3⁺ cTFH frequencies) but inversely correlated with CCR6⁺CXCR3⁻ S-specific cTFH. Principal component analysis (PCA) on immunological variables alone revealed clustering of subjects with stronger and weaker plasma neutralization activity (Fig. 4b). Using a multiple regression approach, we identified high titers of S-specific antibody and low proportions of S-specific cTFH with a TH17-like phenotype (CCR6⁺CXCR3⁻) as the two most significant predictive factors related to neutralization activity (Fig. 4c). In line with recent reports, we found that neutralizing activity^{20,36}, S-specific antibody^{20,36} and S-specific cTFH responses, but not cTFH phenotypes, associated with participants reporting greater symptom severity (Extended Data Fig. 10).

Efficient elicitation of potent neutralizing antibodies is likely to be critical for effective vaccines against SARS-CoV-2. However, despite near universal detection of antibodies, B cells and T cells specific for S and/or RBD in patients with COVID-19 (refs. ^{20,34,37}), we found that neutralization activity in the plasma ranges widely from relatively potent to negligible, consistent with other reports^{20,36}. Similarly, B and T cell responses targeting the RBD, and in particular the ACE2 interaction site, were markedly less frequent than total responses to S, to the point of being undetectable in some participants. Overall, our data suggest that for some individuals, precise antibody recognition and blockade of the RBD–ACE2 binding site is the principal pathway to generating neutralizing antibody. However, the disconnect between plasma neutralizing titers and anti-RBD immunity in many individuals suggests that sufficient non-RBD epitope targets exist to constitute an alternative pathway to similar virus neutralization outcomes.

Direct assessment of key immunological events in lymphoid tissues after immunization is challenging in humans, making surrogate biomarkers of effective immunization in the blood especially informative. Circulating S-specific cTFH elicited by infection correlated with both S-specific B cell and antibody responses, with the limited CD4 T cell epitopes localized to the RBD a potential limitation for RBD-based vaccine strategies. S-specific cTFH exhibits a clear phenotypic bias toward a CCR6⁺CXCR3⁻ phenotype (cTFH17), previously reported for other viral glycoproteins³⁸ and similarly observed within cTFH specific for HKU1 spike in our cohort. Notably, increased frequencies of both cTFH1 (CCR6⁺CXCR3⁺) and cTFH2

(CCR6⁻CXCR3⁻) were associated with patients with the highest plasma neutralizing activity. Promotion of cTFH1 responses is well characterized for influenza vaccines^{21,32,39} and in some chronic infections^{40,41}, where elevated frequencies correlate with robust neutralizing antibody responses. However, the functional significance of CXCR3⁺ cTFH in SARS-CoV-2 infection is currently unclear. Given the considerable scientific interest in predicting the biogenesis of protective immunity against SARS-CoV-2, our study suggests that B cell and cTFH frequencies and phenotypes could constitute informative biomarkers of immune function for assessment of upcoming clinical trials of new vaccines targeting S. The small cohort size and lack of epitope-level resolution are limitations of the current study. However, future studies in expanded cohorts will facilitate in-depth phenotypic definition of S-specific B and cTFH populations using single-cell sequencing technologies, clarify connections between cTFH and lymph node counterparts and explore interplay between cTFH phenotype and neutralizing outcomes in response to different vaccine platforms and adjuvants.

Methods

Ethics statement. The study protocols were approved by the University of Melbourne Human Research Ethics Committee (2056689), and all associated procedures were carried out in accordance with approved guidelines. All participants provided written informed consent in accordance with the Declaration of Helsinki.

Subject recruitment and sample collection. Patients who had recovered from COVID-19 and healthy controls were recruited through contacts with the investigators and invited to provide a blood sample. Characteristics of SARS-CoV-2 convalescent patients and healthy controls are provided in Extended Data Fig. 1. For all participants, whole blood was collected with sodium heparin anticoagulant. Plasma was collected and stored at -80°C , and PBMCs were isolated via Ficoll-Paque separation, cryopreserved in 10% DMSO/FCS and stored in liquid nitrogen.

Expression of coronavirus proteins and hACE2. A set of proteins was generated for serological and flow cytometric assays. All unique materials are readily available from the authors. The ectodomain of SARS-CoV-2 (isolate WHU1; residues 1–1,208) or HKU1 S protein (isolate N5; residues 1–1,290) were synthesised with the furin cleavage site removed and P986 and P987 stabilization mutations⁴², a C-terminal T4 trimerisation domain, Avitag and His-tag, expressed in Expi293 cells and purified by Ni-NTA affinity and size-exclusion chromatography using a Superose 6 16/70 column (GE Healthcare) (Supplementary Fig. 4). SARS-CoV S was biotinylated using BirA (Avidity). The SARS-CoV-2 RBD⁴³ with a C-terminal His-tag (residues 319–541; provided by Florian Krammer) was similarly expressed and purified. SARS-CoV RBD (residues N321–P513) with a C-terminal Avitag and His-tag was expressed in Expi293 cells and purified by Ni-NTA, biotinylated using BirA (Avidity) and purified by size-exclusion chromatography using a Superdex 75 (GE Healthcare). The human (residues 19–613) and mouse (residues 19–615) ACE2 ectodomain with C-terminal His-tag (provided by Merlin Thomas) were expressed in Expi293 cells and purified using Ni-NTA and size-exclusion chromatography (Supplementary Fig. 5). Antigenicity of coronaviral proteins was assessed by binding to immune sera, anti-RBD mAbs CR3022 and 4B or human and mouse ACE2 (Supplementary Fig. 6). The glycosylation profile of recombinant S proteins (Supplementary Fig. 6) was assessed using mass spectrometry as previously described⁴⁴ by SP3 protein clean-up⁴⁴ and trypsin in-solution digestion. Purified peptides were de-salted and then separated using a two-column chromatography setup comprising a PepMap100 C18 20 mm $\times$ 75 μm trap and a PepMap C18 500 mm $\times$ 75 μm analytical column on Dionex Ultimate 3000 UPLC (Thermo Fisher). Samples were concentrated onto the trap column at $5\mu\text{l min}^{-1}$ with Buffer A (2% acetonitrile and 0.1% formic acid) for 6 min and infused into a Q-Exactive Plus Mass Spectrometer (Thermo Fisher) at 300 nl min^{-1} via the analytical column. Next, 125-min gradients were used altering the buffer composition from 2% Buffer B (80% acetonitrile and 0.1% formic acid) to 28% B over 95 min, then from 28% B to 40% B over 10 min and then from 40% B to 100% B over 2 min. The composition was held at 100% B for 3 min, then dropped to 3% B over 5 min and held at 3% B for another 10 min. The Q-Exactive Plus Mass Spectrometer was operated in a data-dependent mode automatically switching between the acquisition of a single Orbitrap MS1 scan (70,000 resolution, AGC of 3×10^6) followed by 15 data-dependent HCD MS2 events (35,000 resolution; stepped NCE 28, 30 and 32; maximum injection time of 125 ms and AGC of 2×10^6) with 30-s dynamic exclusion enabled.

The identification of glycoforms was accomplished using Byonic (Protein Metrics, version 3.5.3 (ref. 45)). MS raw files were searched with an MS1 tolerance of ± 5 ppm, and a tolerance of ± 20 ppm was allowed for HCD MS2 scans. Searches were performed using cysteine carbamidomethylation as a fixed modification and methionine oxidation as a variable modification, in addition to allowing N-linked glycosylation on asparagine. The default Byonic N-linked glycan database, which is composed of 309 mammalian N-glycans compiled, was used. The protease specificity was set to full trypsin specificity, and a maximum of two miss-cleavage events was allowed. Data were searched against the expected protein sequence. The search was filtered to a 1% protein false discovery rate as set in the Byonic parameters, with the final results filtered to remove glycopeptide assignments with Byonic score below 300 (double the cutoff score suggested by Lee et al.⁴⁶) to remove low-quality glycopeptide assignments. Data are available via ProteomeXchange with identifier PXD019163.

ELISA. Antibody binding to coronavirus S or RBD proteins was tested by ELISA. Next, 96-well Maxisorp plates (Thermo Fisher) were coated overnight at 4°C with $2\mu\text{g ml}^{-1}$ recombinant S or RBD proteins. After blocking with 1% FCS in phosphate-buffered saline (PBS), duplicate wells of serially diluted plasma were added and incubated for 2 h at room temperature. Plates were washed before incubation with 1:20,000 dilution of HRP-conjugated anti-human IgG (Sigma) for 1 h at room temperature. Plates were washed and developed using TMB substrate (Sigma), stopped using sulphuric acid and read at 450 nm. Endpoint titers were calculated as the reciprocal serum dilution giving signal $2 \times$ background using a fitted curve (4 parameter log regression).

ACE2–RBD inhibition ELISA. An ELISA was performed to measure the ability of plasma antibodies to block interaction between recombinant human

ACE2 and RBD proteins. Next, 96-well Maxisorp plates (Thermo Fisher) were coated overnight at 4°C with $8\mu\text{g ml}^{-1}$ of recombinant RBD protein in carbonate-bicarbonate coating buffer (Sigma). After blocking with PBS containing 1% bovine serum albumin (BSA), duplicate wells of serially diluted plasma (1:25 to 1:1,600) were added and incubated for 1 h at room temperature. Plates were then incubated with $1.5\mu\text{g ml}^{-1}$ of biotinylated recombinant ACE2 protein for 1 h at room temperature followed by incubation with HRP-conjugated streptavidin (Thermo Fisher) for 1 h at room temperature. Plates were developed with TMB substrate (Sigma), stopped with 0.15 M sulphuric acid and read at 450 nm.

Microneutralization assay. SARS-CoV-2 isolate CoV/Australia/VIC01/2020 (ref. 47) was passaged in Vero cells and stored at -80°C . Plasma was heat inactivated at 56°C for 30 min. Plasma was serially diluted 1:20 to 1:10,240 before the addition of 100 TCID₅₀ of SARS-CoV-2 in MEM/0.5% BSA and incubation at room temperature for 1 h. Residual virus infectivity in the plasma/virus mixtures was assessed in quadruplicate wells of Vero cells incubated in serum-free media containing $1\mu\text{g ml}^{-1}$ of TPCK trypsin at 37°C and 5% CO₂; viral cytopathic effect was read on day 5. The neutralizing antibody titer was calculated using the Reed–Muench method, as previously described^{18,19}.

Flow cytometric detection of SARS-CoV-2-reactive B cells. Probes for delineating SARS-CoV-2 S-specific B cells within cryopreserved human PBMCs were generated by sequential addition of streptavidin-phycoerythrin (PE) (Thermo Fisher) to trimeric S protein biotinylated using recombinant Bir-A (Avidity). Biotinylated SARS-CoV RBD was similarly conjugated to streptavidin-BV421 (BD Biosciences). SARS-CoV-2 RBD protein was directly labeled to APC using an APC Conjugation Lightning-Link Kit (Abcam). Cells were stained with Aqua viability dye (Thermo Fisher). Monoclonal antibodies for surface staining included CD19-ECD (J3-119, 1:150) (Beckman Coulter), IgM BUV395 (G20-127, 1:150), CD21 BUV737 (B-ly4, 1:150), IgD PE-Cy7 (IA6-2, 1:500), IgG BV786 (G18-145, 1:75), streptavidin-BV510 (1:600) (BD Biosciences), CD20 APC-Cy7 (2H7, 1:150), CD14 BV510 (M5E2, 1:300), CD3 BV510 (OKT3, 1:600), CD8a BV510 (RPA-T8, 1:1500), CD16 BV510 (3G8, 1:500), CD10 BV510 (HI10a, 1:750) and CD27 BV605 (O323, 1:150) (BioLegend). Cells were washed, fixed with 1% formaldehyde (Polysciences) and acquired on a BD LSR Fortessa or BD Aria II.

Recovery and analysis of B cell receptor sequences. Single S- (S^+RBD^-) and RBD-specific (S^+RBD^+) IgG⁺ B cells were stained as before and sorted using a BD Aria II into 96-well plates, subject to cDNA generation and multiplex PCR and Sanger sequencing, as previously described⁴⁸. Productive, recombined heavy (V-D-J) and light (V-J) chain immunoglobulin sequences were analyzed using IMGT V-quest⁴⁹.

Flow cytometric detection of antigen-specific cTFH and CD4 T cells. Cryopreserved human PBMCs were thawed and rested for 4 h at 37°C . Cells were cultured in 96-well plates at 1×10^6 cells per well and stimulated for 20 h with $5\mu\text{g ml}^{-1}$ of protein (BSA, SARS-CoV-2 S, SARS-CoV-2 RBD and HKU1 S). Selected donors were also stimulated with SEB ($5\mu\text{g ml}^{-1}$) as a positive control. After stimulation, cells were washed, stained with Live/Dead blue viability dye (Thermo Fisher) and incubated in a cocktail of monoclonal antibodies: CD27 BUV737 (L128, 1:50), CCR7 Alexa700 (150503, 1:50), CD45RA PE-Cy7 (HI100, 1:200), CD20 BUV805 (2H7, 1:50), CD14 BUV395 (MOP9, 1:100) (BD Biosciences), CD3 BV510 (SK7, 1:100), CD4 BV605 (RPA-T4, 1:100), CD8 BV650 (RPA-T8, 1:400), CD25 APC (BC96, 1:50), OX-40 PerCP-Cy5.5 (ACT35, 1:50), PD-1 BV421 (EH12.2H7, 1:50), CCR6 BV785 (G034E3, 1:100), CXCR3 PE-Dazzle 594 (G02H57, 1:50) (BioLegend) and CXCR5 PE (MU5UBEE, Thermo Fisher, 1:50). Cells were washed, fixed with 1% formaldehyde and acquired on a BD LSR Fortessa using BD FACS Diva.

Cytokine production after stimulation with overlapping peptide pools (15mers overlapping by 11) was measured by intracellular cytokine staining. Thawed PBMCs were rested for 6 h and then stimulated with DMSO, S1 or S2 peptide pool ($2\mu\text{g ml}^{-1}$ per peptide), individual peptide LLQYGSFCTQLNRAL ($2\mu\text{g ml}^{-1}$) or SEB for 16 h in combination with anti-CD49d/CD28 co-stimulatory antibodies (1:100, BD Biosciences). Golgi block and Golgi plug (BD Biosciences) were added 1 h after stimulation. After stimulation, cells were washed, stained with Live/Dead blue viability dye (Thermo Fisher) and incubated in a cocktail of monoclonal antibodies: CD27 BUV737 (L128, 1:50), CD45RA PE-Cy7 (HI100, 1:200), CD20 BUV805 (2H7, 1:50), CXCR5 BB515 (RF8B2, 1:33) (BD Biosciences); CD3 BV510 (SK7, 1:100), CD4 BV421 (RPA-T4, 1:100), CD8 BV650 (RPA-T8, 1:400), CCR6 BV785 (G034E3, 1:100) and CXCR3 PE-Dazzle 594 (G02H57, 1:50) (BioLegend). Cells were washed, permeabilized with Cytofix/Cytoperm (BD Biosciences) and then stained with IFN- γ APC (B27, 1:100), IL-17A (BL168, 2:25) and TNF APC-Cy7 (Mab11, 1:25) (BioLegend). Cells were washed and acquired on a BD LSR Fortessa using BD FACS Diva.

Statistical analyses. Grouped data are generally presented as median $\pm$ IQR, with groups compared by Wilcoxon or Mann–Whitney U tests using Prism 8.0 (GraphPad). Pairwise correlations were assessed using Spearman's tests in Prism 8.0 (GraphPad). A multiple linear regression was used to determine which

factors can be used to predict the values of microneutralization across 41 patients. A backward model selection method was used by first fitting a model with all variables of interest and gradually removing one variable with the least significant *P* value. For each step, the nested *F* test was used to compare the models (ie, if the removed variable contributed significantly to the fit). This procedure was stopped when a model with only significant predictors was obtained. Confirmatory forward selection methods were also employed, arriving at the same final model. This analysis was performed using the *lm* function in R (version 3.6.3).

Spearman's correlation matrix was calculated using the *rcorr* function in R (version 3.6.3). PCA was performed in R (version 3.6.3) using the *princomp* function by first scaling the variables to have a unit variance. For analysis of disease severity and immunological outputs, a nonparametric Kruskal–Wallis test was used to assess the difference in the mean of the dependent variables (ie, neutralizing activities and immune parameters) across categorical variables (ie, disease severity; all analyses were performed in R (version 3.6.3)). Throughout the manuscript, significance was defined as *P* < 0.05.

Reporting Summary. Further information on research design is available in the Nature Research Reporting Summary linked to this article.

Data availability

The mass spectrometry data that support the findings of this study are available via ProteomeXchange with identifier [PXD019163](https://doi.org/10.1038/s41591-020-0913-5). The authors declare that all other data supporting the findings of this study are available in the paper and the Supplementary Information files.

Characteristics of 41 subjects recovered from COVID-19

Characteristic	Median	IQR
Age, median - years	59	(54-65)
Male sex – no. (%)	24 (59%)	
Time since symptom onset - days	36	(32-40)
Time since +ve nasal swab SAR-CoV2 PCR* - days	32	(28-35)
Illness severity**		
Mild – no. (%)	26 (63.4%*)	
Moderate – no. (%)	10 (24.4%)	
Severe – no. (%)	5 (12.2%)	

* 3 Subjects had a compatible illness and history of exposure but did not have a positive nasal swab

** Illness severity was classified as:

Mild: prominent upper respiratory tract symptoms and not hospitalised.

Moderate: prominent lower respiratory tract symptoms and not hospitalised.

Severe: prominent lower respiratory tract symptoms and requiring hospital care.

Age and sex of 27 healthy control subjects without COVID-19 symptoms

Characteristic	Median	IQR
Age - years	33	(28-36)
Male sex – no. (%)	14 (52%)	

Age and sex of 10 healthy control subjects selected for follow-up

Characteristic	Median	IQR
Age - years	34.5	(31.75-37.5)
Male sex – no. (%)	5 (50%)	

Extended Data Fig. 1 | Demographics and clinical characteristics of recruited COVID-19 patients and healthy control subjects.

Extended Data Fig. 2 | Pre-screen of HCoV-HKU1 serum endpoint titres among a cohort of healthy subjects (N = 27) bled prior to the SARS-CoV-2 pandemic. Data is shown as the median.

Extended Data Fig. 3 | Correlations between antibody binding titres, ACE2/RBD binding inhibition and neutralization activity in plasma from subjects recovered from SARS-CoV-2 infection. a, Spearman's Correlation between endpoint titres of S-specific plasma antibody and the extent of ACE2/RBD binding inhibition, plasma neutralization titres or endpoint titres of RBD-specific plasma antibody ($N = 41$). **b**, Correlation between endpoint titres of RBD-specific plasma antibody and the extent of ACE2/RBD binding inhibition or plasma neutralization activity ($N = 41$). **c**, Correlation between plasma ACE2/RBD binding inhibition and neutralization activity ($N = 41$). All correlations are two-tailed.

Extended Data Fig. 4 | Representative staining of S- and RBD-specific IgD-IgG⁺ B cells. 3 uninfected subjects (left panels) and 6 subjects after recovery from SARS-CoV-2 infection (middle and right panels). CD19⁺IgD-IgG⁺ B cells were identified using gating strategy shown in Supplementary Fig. 1. Binding to SARS-CoV-2 spike and/or SARS-CoV-2 RBD probes was assessed.

Extended Data Fig. 5 | Memory B cell phenotypes in subjects after SARS-CoV-2 infection. a, b, Representative memory B cell phenotypes identified by CD21 and CD27 co-stain of probe⁺CD19⁺IgD⁻ cells (blue) overlaid on CD19⁺IgD⁻ cells (grey) (**a**) and the corresponding frequencies of the four populations in subjects previously infected with SARS-CoV-2 (**b**) (Resting memory—CD21⁻CD27⁺; activated memory—CD21⁻CD27⁻; naïve/CD27^{lo} memory—CD21⁺CD27⁻; atypical B cells—CD21⁺CD27⁺); n.d.—not detected due to absent probe⁺ cells. Memory B cell phenotypes were identified using gating strategy shown in Supplementary Fig. 2.

Extended Data Fig. 6 | Analysis of V gene distribution, somatic mutation and CDR-H3 lengths for S- and RBD-specific BCR sequences. a,b,c, Frequency distributions of human IGHV (**a**), IGKV (**b**) and IGLV (**c**) genes from BCR sequences recovered from S- (red) and RBD-binding (blue) IgG⁺ B cells from recovered COVID-19 patients (N=5) with reference to distribution in cord blood (grey)⁴⁹. Few IGLV sequences for RBD-binding B cells were recovered and are not shown. **d, e,** CDR-H3 (**d**) and somatic mutation (**e**) in S- (red) and RBD-binding (blue) IgG⁺ B cells compared to influenza B HA-specific IgG⁺ B cells recovered after immunisation²³. **f,** Somatic mutation in S- (red) and RBD-binding (blue) IgG⁺ B cells for each individual subject. **d,e,f,** Data are shown as the median.

Extended Data Fig. 7 | cTFH populations in SARS-CoV-2 positive and negative donors. **a**, cTFH frequency (as a proportion of CD4⁺CD45RA⁻ cells) among SARS-CoV-2 negative (n = 10) and SARS-CoV-2 positive (n = 39) donors. **b**, Frequency of antigen-specific cTFH following stimulation with peptide pools spanning S1 (without RBD peptides), S2 or RBD regions of SARS-CoV-2 S in SARS-CoV-2 positive donors (n = 20). **c**, Frequency of IFN γ ⁺, IL-17⁺ or TNF⁺ cells following SEB stimulation among cTFH or Tmem (CD4⁺CD45RA⁻CXCR5⁻) populations in SARS-CoV-2 positive donors (n = 20; Wilcoxon two-tailed test). **d**, CCR6 and CXCR3 expression among bulk cTFH (grey), IFN γ ⁺ (blue) or IL-17⁺ (red) cTFH cells following SEB stimulation in SARS-CoV-2 positive donors (n = 20). **a**, **b**, **d**, Data are shown as the median with interquartile range.

Extended Data Fig. 8 | Peptide-specific cTFH responses in SARS-CoV-2 positive donors. a, A 15-mer peptide derived from SARS-CoV-2 S2, LLQYGSFCTQLNRAL, was found to be immunogenic in 3 SARS-CoV-2 positive subjects (CP39, CP02, CP36). CP12 shown as representative non-responder. **b,** Plots indicate the CCR6/CXCR3 expression among S2 peptide pool- or peptide-specific cTFH for each donor.

Extended Data Fig. 9 | CD4⁺ Tmem responses in COVID patients and controls. **a**, Representative staining of CD134 and CD25 expression following protein or SEB stimulation among CD4 Tmem (CD4⁺CD45RA⁻CXCR5⁻) cells. **b**, Background-subtracted frequencies of SARS-CoV-2 S, SARS-CoV-2 RBD or HCoV HKU1 spike-specific CD4 Tmem cells among SARS-CoV-2 negative (n=10) or SARS-CoV-2 positive (n=39) donors. **c**, IFN γ , IL-17 and TNF responses following stimulation with overlapping peptide pools covering SARS-CoV-2 S1 or S2 domains, or SEB in SARS-CoV-2 positive donors (n=20). **d**, Graphs indicate background-subtracted responses; responses not above background are indicated as 0.001% (n=20). **b**, **d**, Data are shown as the median with interquartile range.

a

Variable (vs Disease severity)	p-values (against a constant model)	Direction
ELISA: SARS-CoV-2 S trimer	0.0117	Mild<Moderate<Severe

Extended Data Fig. 10 | Association of immunological features with disease severity. **a**, Analysis of the relationship between disease severity (mild, moderate or severe) and immunological parameters within the SARS-CoV-2 convalescent cohort. $p < 0.05$ indicated in bold (Kruskal-Wallis test, two-tailed). **b**, Relationship between cTFH, S-specific antibody titre, or microneutralization (MN) titre with disease severity ($n = 26$ mild, $n = 10$ moderate, $n = 5$ severe). Data are shown as the median with interquartile range.

Reporting Summary

Nature Research wishes to improve the reproducibility of the work that we publish. This form provides structure and transparency in reporting. For further information on Nature Research policies, see our [Editorial Policies](#) and the [Editorial Policy Checklist](#).

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a	Confirmed
☐	☒ The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement
☐	☒ A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
☐	☒ The statistical test(s) used AND whether they are one- or two-sided
<i>Only common tests should be described solely by name; describe more complex techniques in the Methods section.</i>
☐	☒ A description of all covariates tested
☐	☒ A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
☐	☒ A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
☐	☒ For null hypothesis testing, the test statistic (e.g. F , t , r) with confidence intervals, effect sizes, degrees of freedom and P value noted
<i>Give P values as exact values whenever suitable.</i>
☒	☐ For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
☒	☐ For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
☐	☒ Estimates of effect sizes (e.g. Cohen's d , Pearson's r), indicating how they were calculated

Our web collection on [statistics for biologists](#) contains articles on many of the points above.

Software and code

Policy information about [availability of computer code](#)

Data collection Flow cytometry data was collected using BD FACS Diva

Data analysis Data were analysed in Prism 8.0, r version 3.6.3, FlowJo v10, Byonic v3.5.3, and IMGT V-quest

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Research [guidelines for submitting code & software](#) for further information.

Data

Policy information about [availability of data](#)

All manuscripts must include a [data availability statement](#). This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A list of figures that have associated raw data
- A description of any restrictions on data availability

The mass spectrometry data that support the findings of this study are available via ProteomeXchange with identifier PXD019163. The authors declare that all other data supporting the findings of this study are available within the paper [and its supplementary information files].

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

☒ Life sciences ☐ Behavioural & social sciences ☐ Ecological, evolutionary & environmental sciences

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size	Samples from convalescent COVID-19 patients were collected at a timepoint approximately 32 days from the time of SARS-CoV-2 positive PCR test. Due to the exploratory nature of the study, the 41 samples represent the degree of recruitment that could be conducted in a reasonable timeframe, while allowing for a sufficient sample size for the correlation and regression analysis linking plasma neutralisation activity to immune parameters.
Data exclusions	Two individuals were excluded from the analysis of non-cTfh memory CD4 T cells, as those individuals displayed T cell staining patterns consistent with the small proportion of humans who, due to genetic polymorphism, do not downregulate CD45RA upon T cell activation. This prevented analysis of the CD45RA- memory T cell population.
Replication	Flow cytometry assays were performed over multiple independent experiments, with appropriate positive and negative controls. T cell stimulation data was successfully confirmed with peptide pool stimulation in a subset of 20 SARS-CoV-2 convalescent donors. B cell probe staining was successfully replicated in 5 donors in two independent experiments.
Randomization	Participants in the SARS-CoV-2 positive group were identified by clinical symptoms and/or positive SARS-CoV-2 PCR test. Uninfected control samples were collected from healthy donors prior to the spread of SARS-CoV-2 within Australia. Due to the nature of the study, allocation to the study groups was not random, and could not control for covariates that may differ between groups. This had minimal impact on the study results, as the majority of analysis is performed within the SARS-CoV-2 convalescent group.
Blinding	Neutralisation assays were performed with the investigators blinded to the sample group allocation. Blinding was not performed during flow cytometry gating analysis because gates were applied in an unbiased manner across all samples.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Materials & experimental systems

n/a	Involved in the study
☐	☒ Antibodies
☐	☒ Eukaryotic cell lines
☒	☐ Palaeontology and archaeology
☒	☐ Animals and other organisms
☐	☒ Human research participants
☒	☐ Clinical data
☒	☐ Dual use research of concern

Methods

n/a	Involved in the study
☒	☐ ChIP-seq
☐	☒ Flow cytometry
☒	☐ MRI-based neuroimaging

Antibodies

Antibodies used	B cell staining: CD19-ECD (J3-119, #IM2708U) (Beckman Coulter), IgM-BUV395 (G20-127, #563903), CD21-BUV737 (B-ly4, #564437), IgD-Cy7PE (IA6-2, #561314), IgG-BV786 (G18-145, #564230) (BD Biosciences), CD20 APC-Cy7 (2H7, #302314), CD14-BV510 (M5E2, #301841), CD3 BV510 (OKT3, #317332), CD8a-BV510 (RPA-T8, #301048), CD16-BV510 (3G8, #302048), CD10-BV510 (HI10a, #312220), CD27-BV605 (O323, #302829) (Biolegend). T cell staining: CD27 BUV737 (L128, #612829), CCR7 Alexa700 (150503, #561143), CD45RA PeCy7 (HI100, #560675), CD20 BUV805 (2H7, #564917), CD14 BUV395 (MOP9, #563561) (BD Biosciences), CD3 BV510 (SK7, #344828), CD4 BV605 (RPA-T4, #300556), CD8 BV650 (RPA-T8, #301042), CD25 APC (BC96, #302610), OX-40 PerCP-Cy5.5 (ACT35, #350010), PD-1 BV421 (EH12.2H7, #329920), CCR6 BV785 (G034E3, #353422), CXCR3 Pe-Dazzle594 (G02H57, #353736) (Biolegend), and CXCR5 PE (MU5UBEE, #12-9185-42, ThermoFisher). T cell ICS: CXCR5 BB515 (RF8B2, #564624, BD Biosciences), anti-CD49d/CD28 (L25, L293, #347690, BD Biosciences); CD4 BV421 (RPA-T4, #300532, Biolegend), IFNγ APC (B27, #506510); IL-17A (BL168, #512326) and TNF APC-Cy7 (Mab11, #502944) (Biolegend). ELISA: HRP-conjugated polyclonal anti-human IgG (#P0214, Dako)
Validation	All flow cytometry antibodies used are commercial antibodies, reported by the manufacturer to be validated for use in flow

Validation

cytometry using human cells. HRP-conjugated anti-human IgG is validated by the manufacturer for the detection of human IgG by ELISA.

Eukaryotic cell lines

Policy information about [cell lines](#)

Cell line source(s)

Vero cells were obtained from ATCC; Expi293F cells were obtained from ThermoFisher (#A14527)

Authentication

None of the cell lines used were authenticated

Mycoplasma contamination

Vero cells tested mycoplasma negative. Expi293 cells were not tested for mycoplasma.

Commonly misidentified lines
(See [ICLAC](#) register)

N/A

Human research participants

Policy information about [studies involving human research participants](#)

Population characteristics

The SARS-CoV-2 cohort was a median of 59 years old and was 59% male. Age, time since SARS-CoV-2 PCR test and time since symptom onset were included in the regression analysis and model building. The uninfected control cohort was a median of 33 years old, and 52% male, and were not ill at the time of sample collection.

Recruitment

Participants were recruited by contact with the study investigators, and through word of mouth among SARS-CoV-2 infection clusters. Participants may have self-selected for people with a greater interest in COVID-19 infection, but this is unlikely to affect the results of the study.

Ethics oversight

University of Melbourne Human Research Ethics Committee (#2056689)

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Flow Cytometry

Plots

Confirm that:

- ☒ The axis labels state the marker and fluorochrome used (e.g. CD4-FITC).
- ☒ The axis scales are clearly visible. Include numbers along axes only for bottom left plot of group (a 'group' is an analysis of identical markers).
- ☒ All plots are contour plots with outliers or pseudocolor plots.
- ☒ A numerical value for number of cells or percentage (with statistics) is provided.

Methodology

Sample preparation

PBMC were isolated from whole blood and cryopreserved. Samples were thawed in batches and either stimulated (T cell data) or immediately stained (B cell data)

Instrument

Samples were acquired on a BD LSR Fortessa, or sorted on a BD FACS Aria III

Software

Samples were acquired using BD FACS Diva, and analysed using FlowJo version 10

Cell population abundance

B cells were single-cell sorted for BCR sequencing, so purity is not relevant

Gating strategy

The gating strategies for each experiment are shown in Supplementary Materials. B cells were gated based on FSC/SSC, singlets, live cells with exclusion for T/NK/monocyte markers, then expression of CD19, and gated as IgD-, IgM+/-, IgG+/- and analysed for binding to SARS-CoV-2 probes, with expression of CD21/CD27. T cells were gated based on FSC/SSC, singlets, live cells with exclusion of CD14 and CD20, then CD3+gdTCR-, CD4+CD8-CD45RA- cells. cTFH were defined as CXCR5+, and Tmem as CXCR5-, with subsequent phenotyping based on CCR6 and CXCR3.

- ☒ Tick this box to confirm that a figure exemplifying the gating strategy is provided in the Supplementary Information.
