Social and cognitive factors influencing commercial chicken farmers' antimicrobial usage in Bangladesh

Tasneem Imam¹, Justine S. Gibson¹, Suman Das Gupta¹, Mohammad Foysal², Shetu B. Das², Md Ahasanul Hoque², Guillaume Fournié³ & Joerg Henning¹

Adapting the Social Cognitive Theory framework, we conducted a cross-sectional study on 137 commercial chicken farms in Bangladesh to investigate factors influencing the *behaviour* of farmers towards the application of antimicrobials to their birds. Almost all farmers used antimicrobials to treat poultry diseases, while 38.6% also were using them to promote healthy growth of chickens and 10.2% to increase egg production or improve meat quality. Using Structural Equation Modeling (SEM), we identified that inappropriate usage of antimicrobials (*behaviour*) was strongly driven by farmers' short-term *goals* to maintain the health of their chickens in a production cycle ($\beta = 0.813$, $p = 0.029$), rather than long-term concerns. Farmers' perception about their ability to control antimicrobial administration based on their skills and opportunities (*self-efficacy*) marginally influenced the short-term *goals* of antimicrobial usage ($\beta = 0.301$, $p = 0.073$). The results of this study can be used to develop targeted education programs for farmers, to reduce the application of antimicrobials in their poultry flocks.

Antimicrobial resistance is considered as a global threat to human health¹ and action plans to tackle this problem have been developed by the World Health Organisation (WHO)². To investigate the awareness towards antimicrobial resistance among public health and agriculture experts as well as policymakers, WHO conducted a survey of 9772 participants from 12 countries (China, Vietnam, India, Indonesia, Egypt, Sudan, Russian Federation, Siberia, Barbados, Mexico, Nigeria and South Africa) between September and October 2015³. About 57% of the respondents indicated that 'there is not much people like them can do to stop resistance development' and 44% believed that 'resistance is only a problem for those who take antimicrobials regularly'. The report also highlighted that people of lower income countries are less aware of antimicrobial resistance compared to people of higher income countries³.

Inappropriate use of antimicrobials in food animals has contributed to the emergence of antimicrobial resistance⁴. Misconceptions about antimicrobial usage are common among farmers, and disease occurrence due to poor biosecurity⁵ and a lack of strategic vaccinations⁶ might influence farmers' behaviour towards antimicrobial applications. For example, some farmers believe that antimicrobials could improve the immunity of chickens and, that antimicrobial usage for disease prevention or growth promotion may not result in antimicrobial resistance⁷. Furthermore, some farmers believe that antimicrobials should be administered without veterinarians' advice⁷ and that preventive usage of antimicrobial is more important than improving biosecurity⁸. Other perceptions of farmers are that antimicrobials can be prescribed by traders⁹, that the use of multiple antimicrobials is important to control diseases on farms⁷, that antimicrobial usage on food animals does not have any impact on human health¹⁰ and that antimicrobials can be used without adhering to withdrawal periods¹¹.

The decision-making process of farmers to implement or to not implement appropriate management practices is complex and different approaches have been used to analyse farmer's behaviours and the factors associated with these behaviours. The knowledge, attitude, and practice (KAP) approach has been applied in the context of antimicrobial usage^{7,12,13}. KAP studies are popular as they are easy to design, less time consuming and less costly than in-depth qualitative studies^{14,15}. However, KAP approaches has been criticized by social scientists as the behaviour of a person represents interlinked characteristics of this person's knowledge, beliefs, emotions and values, which are not as easily captured in responses to separate individual questions in a KAP questionnaire¹⁵.

Antimicrobials help chickens to recover from disease (Goal2)*	0.0 (0)	0.0 (0)	0.7 (1)	87.6 (120)	11.7 (16)
Antimicrobials help increase egg production or improving the quality of the chicken meat (Goal3)*	5.1 (7)	73.0 (100)	11.7 (16)	8.0 (11)	2.2 (3)

Table 1. Percentage (N) of responses to statements ('observed variables') provided by commercial layer and broiler chicken farmers in Chattogram, Bangladesh. Abbreviations in brackets (Beh, SEff and Goal) represent individual statements in the questionnaire for which responses were captured in the interview (see Table S1 for more details). *Recoded for analysis.

Furthermore, knowledge (which is a key component evaluated in KAP studies) is only one of many factors that influence how people seek to address a problem; thus, a direct relationship between knowledge and behaviour cannot be assumed. To change behaviour, extension and intervention programmes need to address additional factors ranging from sociocultural to environmental and economic components, which are usually not captured in KAP studies^{16–20}.

On the other hand, theoretical concepts such as the Health Belief Model²¹, Theory of Reasoned Action²², Theory of Planned Behaviour²³ and Protection Motivation Theory²⁴ and Social Cognitive Theory^{25,26} represent applied psychological frameworks that do allow to comprehensively analyse behaviours and factors influencing them²⁵. The 'Social Cognitive Theory' in particular has been used to describe social and cognitive factors that impact human behaviour^{25,26}. This framework has also been used to study populations in which interventions of 'healthier habits' were introduced. For example, it has been applied to describe how technological innovations can change the behaviour of diabetic people²⁵, how vocational services for people with psychiatric disorders can be improved²⁷, how web-based learning systems for students can be enhanced²⁸, and how behaviour relating to physical activities can be improved²⁹. This framework has also been applied to investigate farmers' behaviour towards water conservation³⁰ and to explore the usage of climate forecasts to make decisions about crop management³¹.

Therefore, we considered the 'Social Cognitive Theory' as a flexible and applied psychological framework to evaluate the behaviour of commercial farmers towards administration of antimicrobials in their chicken flocks.

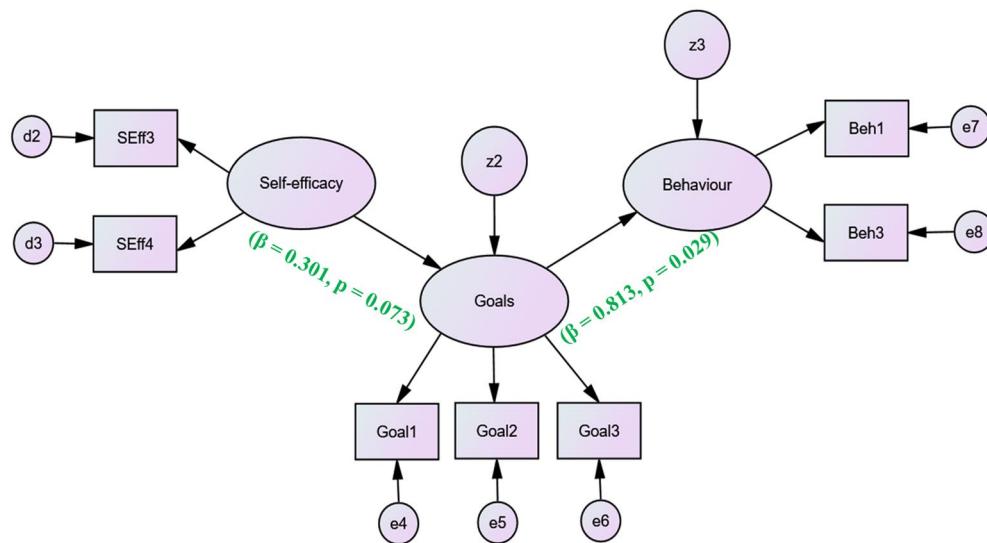

Results

The study population included 137 commercial layer and broiler chicken farmers operating in Chattogram, Bangladesh, with 83 farmers raising broiler chickens and 54 laying hens. Most broiler (98.8%, 82/83) and all layer farmers (100.0%, 54/54) were male. Most layer farmers (61.1%, 33/54) and about half of the broiler farmers (49.4%, 41/83) had ≥ 10 years of farming experience. More layer farmers (92.6%, 50/54) had a secondary level of education compared to broiler farmers (78.3%, 65/83)³².

Frequency statistics of all the responses collected on a five-point Likert scale for each 'observed variable' under the 'latent constructs' are presented in Table S1, while the frequency statistics of the responses for each 'observed variable' maintained in the final Structural Equation Model (SEM) under the 'latent constructs' (*behaviour, self-efficacy and goals*) are shown in Table 1. The *behaviour* of farmers to use antimicrobials in their chicken flocks was the outcome 'latent construct'.

Behaviour. About half (51.1%, 70/137) of farmers either agreed or strongly agreed that they used an increased dose of antimicrobials when they observed more chicken getting sick or dying (Table 1). About a third of farmers (32.8%, 45/137) acknowledged to stock a range of antimicrobials on their farms even if there was no need to use them.

Self-efficacy. The majority of farmers (94.8%, 130/137) indicated that an enforcement of stronger laws is needed to reduce antimicrobial usage. Most farmers (84.6%, 116/137) also indicated that they would invest time and money to further improve farm hygiene and biosecurity to reduce the usage of antimicrobials on their farms.

Indirect effect: Self-efficacy → Goals → Behaviour: $\beta = 0.245 (p=0.130)$

Abbreviations (Beh, SEff and Goal) represent individual statements in the questionnaire for which responses were captured in the interview (see Table S1 for more details).

Figure 1. Final Structural Equation Model describing farmers' *behaviour* towards antimicrobial administration on commercial chicken farms in Chattogram, Bangladesh that is based on the 'Social Cognitive Theory' framework²⁵. 'Observed variables' are presented in rectangles and the 'latent constructs' are presented in ovals. Both 'd' and 'e' represent errors of measurements, while 'z' represents the residuals of the latent constructs.

Goals. Almost all farmers (99.3%, 136/137) highlighted that antimicrobials help chickens to recover from disease. About a third (38.6%, 53/137) of farmers mentioned that antimicrobials promote a healthy growth of chickens, while a small proportion of them (10.2%, 14/137) indicated that antimicrobials help to increase the egg production or improve the quality of the chicken meat.

Structural Equation Modeling (SEM)

Using confirmatory factor analysis (CFA) in the measurement part of the SEM, no significant association was identified for any of the 'observed variables' with the latent construct *socio-structural factors* ($p > 0.05$). Therefore, the latent construct *socio-structural factors* was not included in the structural part of the SEM.

Using path analysis in the structural part of the SEM, the latent constructs *outcome expectations*, *goals*, *self-efficacy*, and *behaviour* (as the outcome variable) were considered. The latent construct *outcome expectations* did not significantly ($p = 0.501$) influence farmers' *behaviour* to use antimicrobials on their farms and was therefore excluded.

The final SEM path is shown in Fig. 1. The results indicate that *behaviour* of commercial chicken farmers to increase the usage of antimicrobials or to have a range of antimicrobials available for usage on farms, increased with their (short-term) *goals* to improve the health of their chickens ($\beta = 0.813, p = 0.029$). *Self-efficacy* had a marginal impact on the goals of farmers to improve the health of their chickens ($\beta = 0.301, p = 0.073$), and had no significant direct impact on *behaviour* of farmers related to antimicrobial usage.

Overall, the data fit the model well ($\chi^2 = 8.724, p = 0.647$; RMSEA < 0.01, CFI = 1.000, SRMR = 0.045).

Discussion

To the best of our knowledge, this is the first published research study that used the 'Social Cognitive Theory' framework to explore social and cognitive factors influencing farmers' *behaviour* towards antimicrobial administration on commercial chicken farms.

Overall, this study found that farmers' *behaviour* is primarily directed by their behavioural *goals*. Commercial chicken farmers were concerned about disease occurrence in their chicken flocks, and farmers' *goals* to maintain the health of their chickens was driving their use of antimicrobials. These results may explain the large number of antimicrobials applied on these farms³² and might help to elucidate similar high usages reported from other Asian countries such as India, Nepal, Thailand, China and Sri Lanka³³.

Bandura highlighted that individual *goals* are considered 'effective' in adapting habits. For example, *goals* were the most important determinant in developing healthy *behaviours* such as stopping smoking, reducing weight and performing exercise³⁴. Our study highlighted that farmers created 'short-term' attainable *goals*²⁵, by focusing mainly on poultry health outcomes and thereby immediate benefits in the current production cycle. Indeed,

recurrent beneficial feedback²⁶ from antimicrobial administration over multiple production cycles might have ‘psychologically’ shaped farmers’ behaviour towards inappropriate antimicrobial application. On the contrary, people only tend to change their behaviour when the outcome of their behavioural set goals is dissatisfaction³⁵. Thus, the administration of antimicrobials could be considered as a ‘comfortable and convenient’ solution for farmers (which might therefore be a behaviour that farmers are unwilling to change) as antimicrobials are readily available over-the-counter without a prescription³³ or directly through feed and chick traders⁹ while being easily applied to chickens through feed or drinking water³⁶. Farmers’ intentions of executing rather ‘short-term’ goals have been also illustrated by the fact, that farmers’ responses under outcome expectations, which represent more ‘long-term’ goals (and concerns), did not influence their behavioural pattern towards antimicrobial usage.

According to the ‘Social Cognitive Theory’, goals are determined by self-efficacy²⁵. In consistency with this theory, we found that self-efficacy marginally impacted farmers’ goals regarding antimicrobial application. It has been described previously that self-efficacy influences peoples’ thinking³⁷ and thereby their goal setting to demonstrate an actual behaviour^{38,39}. We found that most farmers were willing to invest time and money to improve farm biosecurity and they were also in support of strict laws to limit antimicrobial usage.

Previous research has highlighted that poultry farmers in Bangladesh are unable to control disease occurrences themselves through the administration of antimicrobials⁴⁰, but also that antimicrobials are frequently administered to chickens in the absence of clinical signs (24.8% of farms) and without adhering to withholding periods (83.3% of layer and 36.1% of broiler farms)³². Therefore, farmers ability to perform a desired behaviour, of reduced antimicrobial usage, requires adequate training, demonstration, and reinforcement²⁵.

We did not identify ‘observed variables’ that significantly influenced the latent construct ‘socio-structural factors’, which was therefore not included in the final model. It could have been the case that ‘socio-structural factors’ were not sufficiently described by the recorded ‘observed variables’ and other variables might need to be considered in future research. For example, ‘socio-structural factors’ might be related to the availability of vaccinations for chickens⁴¹, the influence of representatives from pharmaceutical companies on farmers⁹, lack of financial capital¹² or the opinions of neighbouring farmers⁴³. Also, due to the cross-sectional nature of this research, we could not confirm (for example through observations) the reported behaviour of farmers, so a validation of the hypothesized causal relationships between ‘latent constructs’ could not be performed. A qualitative data collection approach with in-depth interviews would be helpful to explore the identified behaviour of farmers in more detail.

Overall, the research presented here highlighted the short-term goal oriented behaviour of commercial poultry farmers in Bangladesh. These observations are valuable for policy makers for designing extension programs aiming to implement behaviour changes in regard to antimicrobial administration. However, behaviours of individuals are generally difficult to modify⁴⁴ and innovative strategies are required. WHO has developed a guide for Tailoring Antimicrobial Resistance Programmes (TAP) in order to determine perceived barriers and drivers of behaviour change^{45,46}. Behavioural insights specialists working within the TAP highlighted the importance of cultural and social contexts for changing the behaviour of target populations⁴⁵. Lessons from the TAP are useful for designing programs to change the behaviour of poultry farmers in Bangladesh. For example, farmers are less likely to know the generic names of antimicrobials and they are more familiar with the trade names⁷. Therefore, it is important that extension programs consider the knowledge and social background of Bangladeshi poultry farmers, and that effective and cultural-sensitive communication approaches are developed and applied. There are some existing initiatives in Bangladesh under which training of poultry farmers could be delivered. For example, the Department of Livestock Services (DLS) has set-up the Upazila to Community (U2C) initiative, which aims to empower women in rural communities to improve livestock production and disease control⁴⁷. Furthermore, the Bangladesh AMR Response Alliance (BARA) was created to involve both government agencies and private health professionals to ensure responsible use of antimicrobials at the community level⁴⁷. Tapping into these existing community networks would provide opportunities to deliver training on poultry diseases, biosecurity practices and antimicrobial usage, and overall improve poultry production and might be helpful to change the short-term goal oriented behaviour of commercial chicken farmers.

Materials and methods

The ‘Social Cognitive Theory’ framework. The ‘factors’ or components of the ‘Social Cognitive Theory’ framework are self-efficacy, goals, outcome expectations and socio-structural factors, which directly or indirectly influence behaviour²⁵. Figure 2 depicts the hypothesized paths or relationships between individual factors and how they regulate, or impact behaviour as described by Bandura in 2004²⁵.

While self-efficacy measures the ability of people to successfully overcome challenges to perform a behaviour, outcome expectations measure the expected favourable and unfavourable effects of the behaviour including positive and negative self-evaluative reactions²⁵. Goals, which include short-term attainable objectives guide people’s actions²⁵, while socio-structural factors represent the perceived facilitators and obstacles that influence a behaviour²⁵. Bandura emphasized the importance of self-efficacy to directly influence behaviour of humans, but also to influence the other factors²⁵.

We have conceptualized these ‘factors’ of the ‘Social Cognitive Theory’ in relation to farmer’s behaviour in administering antimicrobials to their chicken flocks and defined these ‘factors’ as follows:

1. Perceived self-efficacy relates to the belief of farmers that they could control the usage of antimicrobials based on their own assessment of their skills and opportunities. For example, the statement ‘I believe that stronger laws and enforcement of the law are needed to reduce antimicrobial usage’ belongs to self-efficacy.

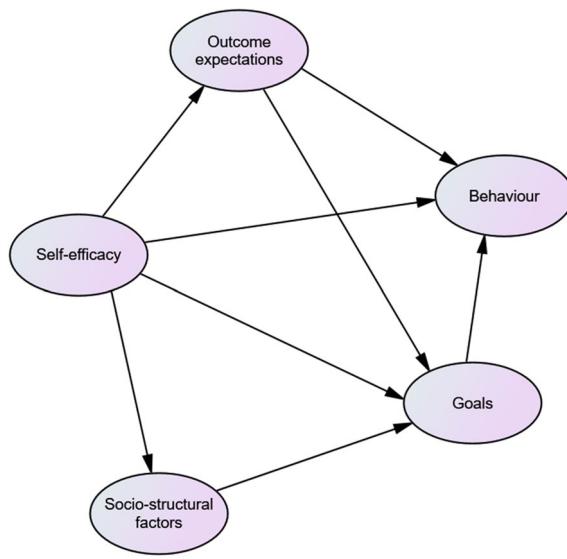

Figure 2. Hypothesized Structural Equation Modeling paths describing farmers' *behaviour* towards the administration of antimicrobials in commercial chicken flocks in Chattogram, Bangladesh.

2. *Outcome expectations* relates to farmers' perceived benefits from using antimicrobials and the effect that antimicrobial administration will have on poultry health, production and human health. An example for an *outcome expectation* would be the statement 'Antimicrobial residues in chicken meat will not harm humans'.
3. *Goals* represent achievable short-term objectives that encourage farmers to administer antimicrobials. 'Antimicrobials help to increase egg production or improve the quality of the chicken meat' is an example statement for *Goals*.
4. *Socio-structural factors* are perceived external facilitators and impediments that encourage or deter farmers to use antimicrobials. 'I am bound to take advice from feed traders because I owe them money (they provide day old chicks, antimicrobials, and feed)' illustrates a statement for *socio-structural factors*.

Study design. A cross-sectional study was used to collect data on farmers' usage and perception of administering antimicrobials to their layer and broiler chicken flocks in the Chattogram district of Bangladesh. The Chattogram district was selected because it is a centre for commercial chicken production in Bangladesh⁴⁸.

First, a sampling frame of 1,748 commercial chicken farms in this district was developed with the help of the Bangladesh District Livestock Services (DLS), feed and chick traders, pharmaceutical representatives, and government and private practitioners⁴⁹. From this sampling frame, 140 commercial chicken farmers from 8 *upazilas* (sub-districts) were selected using simple random sampling (using syntax RANDBETWEEN in Microsoft Excel). Farmers were interviewed between February and May 2019 and 137 of these 140 farmers reported of using antimicrobials and these 137 farmers were in the further analysis. Further details about the sampling approach are provided in³².

Questionnaire. A structured questionnaire was developed to collect data on 'factors' of the 'Social Cognitive Theory' framework. Each 'factor' was evaluated by a series of statements ('observed variables') for which farmers provided responses on a 5-point Likert scale: 'Strongly disagree', 'Disagree', 'Do not know', 'Agree', and 'Strongly agree'.

Data analysis. Structural Equation Modeling (SEM) was used to analyse the dataset. The SEM is comprised of two parts, a measurement and a structural part⁵⁰. In the measurement part of the SEM, statements (or 'observed variables') are used to build each of the separate 'factors' according to 'Social Cognitive Theory'. These 'factors' are termed 'latent constructs' in SEMs. Confirmatory Factor Analysis (CFA) was then applied to identify which of the 'observed variables' would be included in each 'latent construct'. In the structural part of the SEM, path analysis was used to describe the relationship between the causal 'latent constructs' (i.e. *self-efficacy*, *outcome expectations*, *goals*, and *socio-structural factors*) and how they impacted the outcome 'latent construct' *behaviour* (which represented the behaviour of farmers towards antimicrobial usage on their farms). To ensure all 'observed variables' are scaled in the same direction⁵¹, some of the original responses were recoded. The conceptual framework with all collected 'observed variables' informing each 'latent construct' and the relationships between 'latent constructs' is displayed in Fig. S1.

A p-value ≤ 0.05 was selected as cut-off to include 'observed variables' under each of the 'latent constructs' in the CFA and a p-value ≤ 0.1 was selected as cut-off to maintain 'latent constructs' in the path analysis.

The overall model fit was assessed by the chi-square (χ^2) statistic with a p-value < 0.05 as an indicator of good fit⁵². The root mean square error of approximations (RMSEA) was also used, with values < 0.05 indicating a good fit and values up to 0.08 indicating an acceptable fit⁵³. Furthermore, the comparative fit index (CFI) with

values > 0.95 indicating very good fit and ≥ 0.90 an acceptable fit⁵² was also applied. In addition, standard root mean square residuals (SRMR) values ≤ 0.05 were considered indicative of a close-fitting model while values between 0.05 up to 0.10 were suggesting acceptable fit⁵⁴.

Descriptive data analysis was conducted in STATA 16 (StataCorp®, 2019) while the SEM was developed using AMOS 27 (IBM® SPSS® Amos™ 27, 2020).

Ethics approval. Human Ethics Approval for the interviews was obtained from the University of Queensland Institutional Human Ethics Committee on the 7 December 2018 (Approval number: 2018002266). The outlined research with farmers was carried out in accordance with relevant guidelines and regulations (Declaration of Helsinki) and informed consent was obtained from all participants (none of the participants was under 18 years of age).

Data availability

The raw data supporting the conclusions of this research will be made available upon request by the first author of this publication, Tasneem Imam (t.imam@uq.edu.au).

Acknowledgements

We are grateful to the farmers for participating in the research. Also, we thank the Chattogram Veterinary and Animal Sciences University (CVASU) research team for helping with the data collection. We also acknowledge the support provided by GF, MH, and JH through the UKRI GCRF One Health Poultry Hub (Grant no. BB/S011269/1), which represents 1 out of 12 interdisciplinary research hubs funded under the UK government's Grand Challenge Research Fund Interdisciplinary Research Hub initiative.

Author contributions

J.H., G.F., and M.H. designed the research study and obtained the funding for the field research. The questionnaire was developed by TI with inputs from J.H., J.G., and S.G. The data collection strategy was developed by J.H., G.F., M.H., T.I., and S.G. Data collection was conducted by M.F. and S.D. T.I. and S.G. conducted data analysis under the guidance of J.H., G.F., and J.G. T.I. prepared the initial draft, figures, tables, and Supplementary Materials, with edits provided by J.H. and J.G. All authors have read, contributed to, and approved the final version of the manuscript.

Funding

This field data collection was supported by the BALZAC research program (*Behavioural adaptations in live poultry trading and farming systems and zoonoses control in Bangladesh*, BB/L018993/1), a joint research initiative between the Biotechnology and Biological Sciences Research Council, the Defence Science and Technology Laboratory, the Department for International Development, the Economic and Social Sciences Research Council, the Medical Research Council, and the Natural Environment Research Council. TI was supported by an Australia Awards Scholarship.

Competing interests

The authors declare no competing interests.
