Up to now, the ‘hardwired’ neural pathway of the neuro-immune regulation is not fully understood. Here we reported a new neural pathway which links sympathetic nerves with immune cells of the lymphoid tissues. Our results demonstrated that nerve fibers derived from superior cervical ganglion directly targeted only S100⁺ cells in the cervical lymph nodes. Moreover, we found co-expression of neurotransmitters such as norepinephrine, vasoactive intestinal polypeptide and neuropeptide Y in the postganglionic sympathetic nerve endings that innervate S100⁺ cells. Our findings suggested that S100⁺ cells serve as a neuro-immune cross-talker in lymph organs that may play a significant role in transmitting signals of nervous cells to targeted immune cells. The new findings provide better understanding of the cross-talk mechanism between the nervous system and the immune system.

Increasing amounts of evidence showed that the communication between nervous and immune system is essential for the modification of immunological function^{1,2}. There are two pathways involved in this two-system cross-talk: the hypothalamic-pituitary-adrenal (HPA) axis and the sympathetic nervous system (SNS)^{3,4}. The SNS has been previously shown to be involved in neuro-immuno-modulation in addition to the HPA axis. Especially, anatomical and cellular studies have revealed the origin and distribution of sympathetic nerves that supply lymphoid tissues, and shown the expression of neurotransmitters and neuropeptide receptors on immunocompetent cells^{5,6}. However, the functional link between sympathetic nerve endings and immune cells is not fully understood. The mechanism underlying signal transmission from the central nerve system (CNS) to immune cells is also unclear. Thus, this study was to investigate and map the neuro-immunal pathway between nerve fibers and their target cells using Fluoro-Ruby anterograde tracking of sympathetic nerve endings, immunofluorescence labeling and three-dimension reconstruction analysis. Our results provided compelling morphological evidence for better understanding of the ‘hardwired’ neural pathways of the neuro-immune regulation.

Results

We performed the anterograde tracking for sympathetic nerve (SN) fibers which innervate cervical lymph nodes in Sprague-Dawley (SD) rat using Fluoro-Ruby (FR) (Supplementary Fig. 1). On 14 days after one side of the superior cervical ganglion (SCG) was injected with FR, the frozen sections from ipsilateral cervical lymph nodes was examined with laser scanning confocal microscopy. The micrographs showed that most SN fibers to be traced were found within the cortex, paracortex and medulla of lymph nodes, where lymphocytes reside, recognize antigen, and activate, but in the nodular regions and germinal centers were sparse (Fig. 1-A). Interestingly, all the FR-labeled SN endings appeared to directly target one particular population of cells in lymph nodes (Fig. 1-B and 1-C). The FR-targeted cells were large in size and mononucleated with light nuclear density in DAPI staining (Fig. 1-B and 1-C). In order to prove the FR labelings of SN fibers resulting from axonal transport rather than simply free diffusion, we injected 1 µl of 30% FR into the location where the SCG was after SC ganglionectomy. Results showed that FR signals distributed irregularly in the diffusion between cells (Supplementary Fig. 2), but not surrounded the nucleus of particular cells in the lymph node as experimental group shown in Fig. 1. Moreover, we also performed retrograde tracing of sympathetic neurons in SCG by injecting Fluoro-Gold (FG) to cervical lymph nodes. The results showed FG signals displaying in neurons of SCG, confirming connection between SCG and the adjacent lymph nodes (Supplementary Fig. 3).

Figure 1 | Distribution of FR-labeled sympathetic nerve fibers in cervical lymph nodes. One side of superior cervical ganglion (SCG) was injected with 1 μ l of 30% FR. On day 14 after injection, the ipsilateral cervical lymph nodes were moved, fixed and embedded; the frozen sections (15–25 μ m) cut in cross-section were then examined. (A) Contrast (A1) and fluorescence microscopy (A2) revealed that most sympathetic fibers with FR stain (red) appeared within the cortex, paracortex and medulla of the lymph node, but scarcely in the nodular regions and germinal centers (arrows; 100 $\times$ magnification). (B) Amplified micrograph displayed that FR-labeled nerve endings surrounded some cells in the lymph node (400 $\times$ Magnification). FR-traced nerve endings (B1); DAPI-labeled nuclei (B2); merged image (B3). (C) Fluorescence images in the area highlighted in B3 were shown on an enlarged scale (C1–C3).

To ascertain the relationship between the SN and the targeted cells in lymph nodes, we labeled the plasma-membrane with fluorescent dye DiO for the lymph node of labeled nerve fibers. Similarly, the results showed that all FR-labeled signals targeted only one type of cells in the lymph node (Fig. 2–A3,A4), and fiber terminal are wrapped by plasma membrane of targeted cell (Fig. 2–B2, B3). Furthermore, the SN nerve-targeted cell was surrounded by several small cells (presumably lymphocytes) (Fig. 2–B4). In order to define the precise structural relationship between the cell membrane of the targeted cell and SN fiber endings, we performed three-dimensional reconstructions and high-resolution SIM fluorescence microscopic image analyses. Our results further confirmed a structural mosaic

between SN endings and the membrane of the innervated cell (Fig. 3–A, B). Partially enlarged micrographs showed that 0.1–0.2 μ m of FR-labeled nerve endings were embedded in the cell membrane of the innervated cell (Fig. 3–C,D and E; Supplementary movie 1 and 2). The connection of SN endings with the targeted cells in lymph nodes appeared to be similar to the classic synaptic contact between neurons and neurons, or neuromuscular junctions. To explore the possible existence of synaptic contact in lymph node, we examined the ultrastructure of a lymph node via a Philips CM-10 transmission electron microscope. The electron micrograph clearly showed that the presence of unmyelinated axons was adjacent to the innervated cells (Supplementary Fig. 4–A, B). Moreover, synaptic vesicles,

Figure 2 | Relationship of labeled sympathetic nerve endings and innervated cells. A plasma membrane dye, DiO, was used to stain the histological section of the lymph nodes labeled with FR and was then examined with confocal microscopy (TCS SP5, Leica). Micrographs showed that FR-labeled nerve endings (red) landed on the surface of certain cells in lymph nodes (A, arrows). These cells are large in size, mononucleated with light nuclear density (DAPI staining). (B) Nerve endings wrapped around the targeted cell (arrows in B2 and B3) on an enlarged scale. The innervated cells were surrounded by lymphocytes (arrow heads in B4). A1 and B1, FR-labeled sympathetic nerve fibers endings; A2 and B2, Dio-labeled cell membranes; A3 and B3, merged images of FR and Dio from A1-A2 and B1-B2, respectively; A4 and B4, merged images of A1-3 and B1-3, respectively.

Figure 3 | Three-dimensional reconstruction and high-resolution SIM observation of labeled-nerve endings and innervated cells. (A, B) 3D reconstruction clearly showed that the labeled nerve endings (red) land on the cell membrane (green) of innervated cells (B, high magnification). (C) A series of single-cell images ($0.4 \mu\text{m}$) acquired by Z-stack scanning from high-resolution SIM (Total internal reflection fluorescence 100×1.49 NA oil immersion, Nikon) revealed a mosaic structure of nerve endings with the membrane of the innervated cell. (D) Enlargement of the image in the area indicated in C2. The enlarged images clearly showed $0.1\text{--}0.2 \mu\text{m}$ of labeled nerve endings in the cell membrane of the innervated cell. (E) 3D reconstruction of a series of images ($0.4 \mu\text{m}$) acquired by Z-stack scanning with high-resolution SIM.

Figure 4 | Fluorescence immunocytochemistry for CD3, CD22 and CD14 with slice labeled by FR. Red fluorescence (A1,B1,C1) is labeled nerve fibers, and green fluorescence (A2,B2,C2) is CD3⁺, CD22⁺ and CD14⁺ cells. A3, B3 and C3 are respectively merged images from CD3⁺, CD22⁺ and CD14⁺ cells and FR-labeled nerve fibers. The merged images showed that labeled nerve fibers were not around CD3⁺, CD22⁺ and CD14⁺ cells (A3, B3, C3 and A4, B4, C4). This immunofluorescence results demonstrated that the nerve fibers from superior cervical ganglion do not target T cells, B cells and macrophages.

mitochondria and smooth endoplasmic reticulum could be seen in a denuded axon (**Supplementary Fig. 4-C, D**), providing supportive evidence for the existence of synaptic structure between nerve endings and the targeted cells.

To identify the type of cells targeted by FR-labeled nerve endings, we performed immunofluorescence staining of specific membrane antigens on the FR-traced lymph node. The results showed that these targeted cells did not express specific differentiation antigens of T cells (CD3), B cells (CD22), or macrophages (CD14) (**Fig. 4-A, 4-B and 4-C**, respectively). Furthermore, these targeted cells did not express surface markers for dendritic cells (DCs) or plasma cells, such as the class II MHC, CD11c, CD103, and CD138 (**Fig. 5-A, 5-B, 5-C and 5-D**, respectively). By contrast, we found that the FR-labeled nerve innervating cells expressed S100 protein, thereby being S100-positive cells (**Fig. 6-A**). We then examined whether the contact between FR-labeled nerve fibers and their targeted cells was synaptic using fluorescence immunohistochemistry of synaptophysin (SYP). The micrographs demonstrated that all innervated cells were positive to SYP staining (**Fig. 6B, C**). The data strongly suggested that the contact between SN endings and S100⁺ cells is a synaptic connection.

To examine which kind of neuropeptides were in FR-labeled nerve fibers, we performed immunofluorescence staining of vasoactive

intestinal polypeptide (VIP), neuropeptide Y and tyrosine hydroxylase. The results showed that these neuropeptides were co-existed in the FR-labeled nerve fibers (**Fig. 7-A, 7-B and 7-C**, respectively). These findings suggested that neurotransmitters such as TH, NPY and VIP are involved in transmitting signals of the nerve fibers projected from SCG to S100⁺ cells in cervical lymph nodes.

Discussion

Growing evidence of functional contacts of nerves with immune cells and tissues challenges the established view of neuro-immune regulation via circulating hormonal and cytokine signals alone^{7,8}. A direct neural involvement in the modification of immunological function indicates that 'hardwired' neural pathways are widespread and important, although homeostasis undoubtedly involves the cooperative interaction of various systems *in vivo*. These studies have demonstrated the importance of 'hardwired' neural pathways, but the direct contact between nerve fibers and immune cells remains unclear. Our study demonstrated for the first time that the nerve fibers derived from SCG targeted only S100⁺ cells in the adjacent cervical lymph nodes. This is an unexpected result. It is very necessary to know the credibility of this result. One natural question on this result is whether the FR signal carried to the cervical lymph node is entirely

Figure 5 | Fluorescence immunocytochemistry for MHCII, CD11c, CD103 and CD138 with slice labeled by FR. Red fluorescence (A1, B1, C1, D1) is labeled nerve fibers, and green fluorescence (A2, B2, C2, D2) is MHCII⁺, CD11c⁺, CD103⁺ and CD138⁺ cells. A3, B3, C3 and D3 are respectively merged images from MHCII⁺, CD11c⁺, CD103⁺ and CD138⁺ cells and FR-labeled nerve fibers. The merged images showed that labeled nerve fibers were not around MHCII⁺, CD11c⁺, CD103⁺ and CD138⁺ cells (A3, B3, C3, D3 and A4, B4, C4, D4). This immunofluorescence results demonstrated that the nerve fibers from superior cervical ganglion also do not target dendritic cells and plasma cells.

due to phagocytosed and free diffusion dye. In order to prove that the FR signal results from axonal transport rather than simply phagocytosed and free diffusion, we have done controlling experiment. The results showed that Fluoro-Ruby distributes irregularly through diffusion between cells (Supplementary Fig. 2), but the FR signal of the anterograde tracking is a regular distribution as shown in Fig. 1-B and 1-C. Another natural question is whether the FR signal is colocalized with the targeted S100⁺ cells. S100 protein is one of the members of EF-hand type Ca²⁺-binding protein family and is involved in a variety of cellular processes such as cell-cycle regulation and differentiation^{9,10}. S100 protein is an immunohistochemical marker for

interdigitating reticular cells (IRC), a subset of dendritic cells, in lymphoid tissues^{11,12}. In order to exclude the possibility of the dendritic cell-associated S100 protein, we have done variety of anti-DC antibody (MHCII, CD11c, CD103 and CD83) expression. Our experimental results show that all FR-labeled nerve endings finally were shown to directly target only S100⁺ cells, which were not express other DC markers (MHCII, CD11c, CD103 and CD83). This evidence strongly suggests that S100⁺ cells are the neuro-immune cross-talker in lymph organs and play a very pivotal role in the neuro-immune cross-talk mechanism. S100⁺ cells might be considered as a bridge between nervous system and immunocytes, which is a con-

Figure 6 | Fluorescence immunocytochemistry of S100 protein and SYP protein. (A) Immunocytochemistry of S100 showed that cells targeted by FR-labeled nerve endings were S100 protein positive (green, arrows). (B) SYP staining showed that labeled nerve endings were completely overlapped with SYP proteins (green, arrows), indicating that labeled nerve endings expressed SYP proteins. (C) Enlarged images in the area indicated in B4. A1, B1 and C1, FR labeled sympathetic nerve fibers; A2, S100 staining; B2 and C2, SYP staining; A3, B3 and C3, merged images of A1-2, B1-2 and C1-2, respectively; A4, B4 and C4, merged images of A1-2-3, B1-2-3 and C1-2-3, respectively.

veying signals transmitted from nervous system. This pattern of the contact between nerve fibers and innervated cells in lymph nodes was rarely exposed in the literature¹³. Whether these cells are IRC or a new type of cells remains unclear and requires further investigations.

To explore the possible existence of synaptic contact in SN endings with the targeted cells in lymph nodes, we examined the ultrastructure of a lymph node via a Philips CM-10 transmission electron microscope. The synaptic vesicles, mitochondria and smooth endoplasmic reticulum could be seen in a denuded axon. Current EM data cannot completely prove a synaptic connection between SN endings and targeted S100⁺ cells. More detailed immune electron microscopy analysis is needed for further study, but this result does not affect to understand that S100⁺ cells are cross-talker between the nervous system and the immune system. The connected form of SN endings with the targeted cells, synapses or non-synapses structure, also needs more further research. Several molecular markers have been used to detect different types of nerve fiber. It has been demonstrated that neurotransmitters of different nerve fiber types, such as norepinephrine, neuropeptide Y (NPY), substance P, vasoactive intestinal peptide (VIP), endogenous opioids, and others modulate immune cells via specific receptors expressed on the cell surface^{14,15}. These neurotransmitters undoubtedly play an important

role in immunomodulating as functional receptors are present on immune cells. At current stage, we know that receptors for neurotransmitters are not uniformly expressed on all immune cells under any condition and it is also dependent on specific micro-environment^{16,17}. Although the mechanism of cross-talking between immune and nervous systems is not well understood, it has been increasingly accepted that there is very strong interaction between cells of the nervous and immune systems^{18,19}. Our results also confirmed that neuropeptides TH, NPY and VIP were co-existed in the FR-labeled nerve fibers. These suggested that the neurotransmitters involved in transmitting signals between nerve fibers projected from SCG and S100⁺ cells in cervical lymph nodes.

In summary, we for the first time provided the anatomical evidence to reveal a novel cross-talk pathway between CNS and immune cells. As a neuro-immune cross-talker, S100⁺ cells in lymph organs may play a critical role in the signal transmission from CNS to immune cells and vice versa. The targeted S100 cells in lymph organs may be a new type of cell populations. The signal transmission from CNS to immune cells is a synaptic interaction, through release of neurotransmitters such as TH, VIP and NPY. More studies are required to disclose the cross-talk mechanism and to further delineate the signals transduction from CNS to S100⁺ cells and to immune cells.

Figure 7 | Fluorescence immunocytochemistry for NPY, VIP and TH with slice labeled by FR. Red fluorescence (A1, B1, C1) is labeled nerve fibers, and green fluorescence (A2, B2, C2) is positive NPY, VIP and TH fibers. A3, B3 and C3 are respectively merged images from NPY⁺, VIP⁺ and TH⁺ fibers. The merged images showed that some labeled nerve endings profiles completely overlap with positive NPY, VIP and TH fibers. This immunofluorescence results demonstrated that labeled nerve endings profiles mostly co-express NPY, VIP and TH (arrows in A3, B3, C3).

Methods

Animals and reagents. Sprague-Dawley rats (250–280 g) were purchased from the Experimental Animal Center of Suzhou University (Suzhou, China). The experimental protocol was approved by the Ethics Committee of Medical College, Suzhou University. The reagents used included: Fluoro-Ruby (FR, Fluorochrom, Inc., USA); primary antibodies against CD14, CD3, CD22, CD11c, MHCII, CD83, CD103, CD138, s100, Synapsin, TH, NPY and VIP from Boster Biotech (Wuhan, China) and secondary antibodies (FITC-IgG; Vector Laboratories, Inc., Burlingame, CA).

Tracer application. Ten male SD rats were used to study interconnection between SN endings and adjacent lymph nodes. Rats were anesthetized with pentobarbital sodium (20 mg/kg, i.p.); then a total volume of 1 μl of 30% Fluoro-Ruby (FR, Fluorochrom, Inc., USA) in distilled water was injected into the SCG using a microsyringe with a removable injection needle (24 gauge, Hamilton, Co., USA). After survival for 14 days, the rats were anesthetized again with pentobarbital sodium (20 mg/kg), followed by transvascular perfusion with 4% paraformaldehyde. The ipsilateral cervical lymph nodes were removed, fixed and cryoprotected. Frozen sections (15–25 μm) were cut in cross-section on a frozen microtome, picked up on gelatin-coated glass slides and examined under confocal microscope.

Tissue processing for electron microscopy. Tissues were fixed by vascular perfusion with 2.5% glutaraldehyde in 0.1 M phosphate buffer solution (PBS, pH 7.4) at a pressure of 120 mmHg. Prior to perfusion, rats were anesthetized with pentobarbital sodium (20 mg/kg). Samples from cervical lymph nodes were embedded in Epon 812 (Fluka, Buchs, Switzerland). For transmission electron microscopy, 50 nm samples were stained with uranyl acetate and lead citrate and examined under a Philips CM-10 transmission electron microscope (TCS SP5, Lecia).

Immunohistochemical staining for CD3, CD14, CD22, CD11c, MHCII, CD103, CD138, S100, TH, NPY and VIP. For immunofluorescence staining, sections obtained from antegrade FR-labeling were rinsed thoroughly in 0.1 PBS, incubated at room temperature for 30 min in 10% normal goat serum and then incubated at 4°C overnight with primary antibodies against CD3, CD14, CD22, S100, CD11c, MHCII, CD103, CD138, NPY and VIP diluted in PBS (1:100–1:500). On the next day, sections were rinsed three times in 0.1 PBS and then incubated in the fluorochrome-conjugated secondary antibodies (FITC-IgG; Vector Laboratories, Inc., Burlingame, CA) diluted in buffer (1:600) for 60 min. After rinsed thoroughly in buffer, counterstained with DAPI and rinsed three times in buffer, sections were mounted and photographed under a confocal microscope. We used DIO (3, 3'-diiodoacetylloxycarbocyanine perchlorate) to stain the cell membrane.
