Although the thermodynamics of protein denaturation at temperatures over 100 °C is essential for the rational design of highly stable proteins, it is not understood well because of the associated technical difficulties. We designed certain hydrophobic mutant proteins of CutA1 from *Escherichia coli*, which have denaturation temperatures (T_d) ranging from 101 to 113 °C and show a reversible heat denaturation. Using a hydrophobic mutant as a template, we successfully designed a hyperthermostable mutant protein ($T_d = 137$ °C) by substituting six residues with charged ones. Thermodynamic analyses of these mutant proteins indicated that the hydrophobic mutants were stabilized by the accumulation of denaturation enthalpy (ΔH) with no entropic gain from hydrophobic solvation around 100 °C, and that the stabilization due to salt bridges resulted from both the increase in ΔH from ion-ion interactions and the entropic effect of the electrostatic solvation over 113 °C. This is the first experimental evidence that has successfully overcome the typical technical difficulties.

The tertiary structures of proteins, which are vital for their physiological functions, are related to amino-acid sequences and stabilized by thermodynamic rules. To elucidate the mechanisms of protein folding and protein stabilization, it is critically important to obtain the thermodynamic parameters of protein denaturation as a function of temperature. One difficulty for studying the stabilization mechanism of proteins with denaturation temperatures above 100 °C is that the heat denaturation of proteins is usually irreversible at temperatures higher than 80 °C^{1–8}, because under these conditions proteins generally aggregate after heat denaturation. Thus, the thermodynamic features of protein stabilization at temperatures above 100 °C are not well understood. One important question in this field is whether the hydrophobic interactions that make the largest contributions to protein stability^{9–13} still occur at temperatures above 100 °C^{14,15}. Next, it is necessary to perform thermodynamic analyses of salt bridges in proteins that have denaturation temperatures above 100 °C, because many proteins from hyperthermophiles seem to be stabilized by an abundance of ion pairs formed by charged residues^{8,16–26}. Thermodynamics of protein denaturation at temperatures over 100 °C is also essentially important for the rational design of hyperthermostable proteins that would be highly useful for industrial and bio-technological processes.

Figure 1. DSC curves of hydrophobic *EcCutA1* mutants with no SH group at pH 9.0. (A) Typical DSC curves of four mutants: *EcCutA1_0SH*, *EcCutA1_0SH_S11V*, *EcCutA1_0SH_E61V*, and *EcCutA1_0SH_S11V/E61V*. Scan rates were 60°C/h. (B) Reversibility of heat denaturation of *EcCutA1_0SH*, *EcCutA1_0SH_S11V*, and *EcCutA1_0SH_S11V/E61V*. The red curves of three proteins are the second runs of DSC, just after the cooling step of the first run (the black curves). Scan rates of both curves were 60°C/h.

The CutA1 protein from the hyperthermophile *Pyrococcus horikoshii* (*PhCutA1*) has an unusually high stability, with a denaturation temperature (T_d) of nearly 150°C at pH 7.0 and an unusually high content of charged residues^{26,27}. The stabilities and structures of CutA1 proteins from species with various growth temperatures have been also examined, including those of *Thermus thermophilus* (*TtCutA1*)²⁸, *Oryza sativa* (*OsCutA1*)²⁸, *Homo sapiens* (brain) (*HsCutA1*)²⁹, and *Escherichia coli* (*EcCutA1*)³⁰. Their T_d values are also unusually high relative to the growth temperatures of each species: 113.9°C for *TtCutA1*, 98.9°C for *OsCutA1*, 96.2°C for *HsCutA1*, and 89.9°C for *EcCutA1*. The X-ray crystal structure of *PhCutA1* clearly resembles those of other CutA1 proteins. The monomeric structure consists of three α -helices and five β -strands. Three monomers are assembled into a trimer through interactions between the edges of three β -strands (Supplementary Fig. 1). This tightly intertwined interaction contributes to the stabilization of the trimer structures for the CutA1 proteins²⁶.

EcCutA1 and its mutants are not heat-reversible³⁰. However, other CutA1 proteins, such as *TtCutA1* and *OsCutA1*, which have fewer cysteine sulfhydryl (SH) groups, exhibit remarkable heat reversibility²⁸. *EcCutA1* has three SH groups per subunit. Therefore, we designed an SH-free *EcCutA1* mutant, referred to as *EcCutA1_0SH* (Cys16 → Ala, Cys39 → Ala, Cys79 → Ala), with the aim of achieving high heat reversibility.

In this study, we used the *EcCutA1_0SH* protein, which has excellent heat reversibility, as a template to design thermostabilized mutants. First, we constructed hydrophobic mutants from *EcCutA1_0SH*, which were effective in our previous work³⁰. Then, to achieve a hyperthermostability comparable to that of *PhCutA1*, we designed ionic mutants in which charged residues were introduced into a hydrophobic mutant (*EcCutA1_0SH_S11V/E61V*) by substitution. We describe our use of these *EcCutA1* mutants to assess the thermodynamic characteristics of proteins at temperatures over 100°C, in regard to both hydrophobic and ion–ion interactions.

Results

Hydrophobic mutants of *EcCutA1* with no SH group. We constructed hydrophobic mutants with no SH groups (*EcCutA1_0SH_S11V*, *EcCutA1_0SH_E61V*, *EcCutA1_0SH_S11V/E61V*), which we expected to increase stability³⁰. Figure 1A shows typical differential scanning calorimetry (DSC) curves of *EcCutA1_0SH* and its hydrophobic mutant without SH groups at pH 9.0. As shown in Fig. 1B, the reheating curve (second scan) of *EcCutA1_0SH* agrees completely with the first scan. The other two proteins also exhibited good reproducibility. These results indicate that the removal of SH groups facilitates excellent reversibility of heat denaturation under these conditions and that we can reliably determine the denaturation enthalpies of these proteins. The denaturation temperature (T_d) of *EcCutA1_0SH* decreased by 4.3°C, relative to that (89.9°C) of *EcCutA1* with SH groups, whereas those of *EcCutA1_0SH_S11V* and *EcCutA1_0SH_E61V* were 103 and 101°C, respectively, which were remarkably improved relative to the template. Furthermore, the T_d of a double mutant, *EcCutA1_0SH_S11V/E61V*, was 113°C, which is 28°C higher than that of the template (Table 1). Hereafter, *EcCutA1_0SH_S11V/E61V* is abbreviated as *Ec0VV*. These changes in stability due to the hydrophobic mutations were comparable to those observed in mutant proteins with SH groups³⁰.

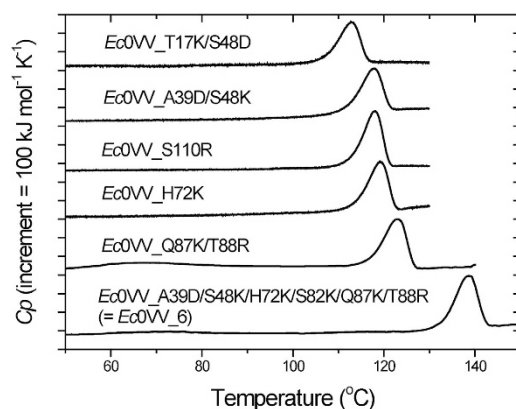

Figure 2. Typical DSC curves of six ionic *EcCutA1* mutants from *Ec0VV* at pH 9.0. The six mutants are *Ec0VV_T17K/S48D*, *Ec0VV_A39D/S48K*, *Ec0VV_S110R*, *Ec0VV_H72K*, *Ec0VV_Q87K/T88R*, and *Ec0VV_6*. Scan rates were 60 °C/h.

Ionic mutants of *EcCutA1_0SH_S11V/E61V* (*Ec0VV*). To examine the thermodynamic parameters of stabilization by ion–ion interaction at temperatures over 100 °C, we constructed several mutant proteins containing substitutions with charged residues, using *Ec0VV* as a template. Ionic mutants, whose denaturation temperatures are improved and whose DSC curves are suitable for thermodynamic analysis, were selected from our pool of stock mutants (Table 1). Typical DSC curves and reversibility curves are shown in Fig. 2 and Supplementary Fig. 2, respectively. Although the T_d of a double mutant, *Ec0VV_T17K/S48D*, was lower than that of the template, it was selected because the T_d was over 100 °C and higher than those of the original single mutants (*Ec0VV_T17K* and *Ec0VV_S48D*) (Table 1). In the case of *Ec0VV_A39D/S48K/H72K/S82K/Q87K/T88R*, which is abbreviated as *Ec0VV_6*, the DSC curve was suitable for analysis (Fig. 2), but the reversibility curve could not be properly obtained due to certain side reactions that occurred at high temperatures. The T_d of *Ec0VV_6* was 136.8 ± 0.9 °C, improved by 23.6 °C with the introduction of six charged residues.

In acidic pH, negatively charged residues of a protein should be protonated, leading to a decrease in conformational stability. In the case of CutA1 from *P. horikoshii*, which is stabilized by many ionic interactions, the T_d of 148.5°C at pH 7.0 is drastically reduced to 75.6°C at pH 2.5, whereas the T_d of CutA1 from *T. thermophilus* changes from 112.8°C at pH 7.0 to 86.6°C at pH 2.5²⁸. To confirm the stabilization resulted from ionic interactions, the stabilities of ionic mutants were examined under acidic conditions at pH 2–3. The T_d values of the ionic mutants monotonically decreased as the pH was lowered, reaching a constant minimum at pH 2–2.5 (Supplementary Table 1). We plotted the T_d shift (T_d value at pH 9.0 vs. pH 2.0–2.5) versus the T_d value at pH 9.0 for several ionic mutants (closed circles in Supplementary Fig. 3). Clearly, the T_d shift became greater as T_d increased. These results suggest that the electrostatic interactions dominates the thermo-stabilization of the ionic mutant proteins.

Temperature dependence of denaturation enthalpy at higher temperatures. The denaturation heat capacity (ΔC_p) is generally assumed to be constant at temperatures below 80°C³¹, but it gradually decreases at higher temperatures¹⁴. Therefore, it is important to elucidate the temperature function of ΔC_p at higher temperatures. To this end, we measured the C_p values of Ec0VV in the native state by DSC at temperatures up to 95°C (Y2 of Supplementary Fig. 4A). Unfortunately, the temperature dependence of C_p values in the denatured state could not be determined experimentally due to the high reversibility of denatured Ec0VV. Alternatively, assuming that the heat-capacity contribution of amino-acid groups is additive, the heat capacity of proteins in the denatured state can be calculated from their amino-acid composition³². Y1 in Supplementary Fig. 4A also shows the temperature function of the heat capacity of Ec0VV in the denatured state, which was estimated from its amino-acid composition using the parameters in Table II of Makhatadze and Privalov³³. Next, we were able to estimate the temperature function of the denaturation heat capacity (ΔC_p) for Ec0VV from these native and denatured C_p values (Y3 of Supplementary Fig. 4A). The temperature function obtained of ΔC_p can be expanded around T_d as a second-order polynomial:

$$\Delta C_p(T) = A + B(T - T_d) + C(T - T_d)^2 \quad (1)$$

Then, the temperature functions of denaturation enthalpy (ΔH) and denaturation entropy (ΔS) can be calculated by the following equations (2) and (3), respectively.

$$\begin{aligned} \Delta H(T) &= \Delta H(T_d) + \int_{T_d}^T \Delta C_p(T') dT' \\ &= \Delta H(T_d) + A(T - T_d) + \frac{B}{2}(T - T_d)^2 + \frac{C}{3}(T - T_d)^3 \end{aligned} \quad (2)$$

$$\begin{aligned} \Delta S(T) &= \Delta S(T_d) + \int_{T_d}^T \frac{\Delta C_p(T')}{T'} dT' \\ &= \Delta S(T_d) + (A - BT_d + CT_d^2) \ln \frac{T}{T_d} + (B - CT_d)(T - T_d) + \frac{C}{2}(T - T_d)^2 \end{aligned} \quad (3)$$

Figure 3A shows the temperature function of ΔH for Ec0VV. The ΔH values of Ec0VV were higher than those at each denaturation temperature of other proteins (*EcCutA1_0SH*, *EcCutA1_0SH_S11V*, and *EcCutA1_0SH_E61V*). If we assume that the temperature function of ΔC_p is not largely affected by the constitution of the protein, this observation indicates that stabilization of hydrophobic mutants at residue positions 11 and 61 is mainly caused by enthalpic effects.

The temperature function of ΔC_p for Ec0VV_6 was also determined using the native C_p values (Supplementary Fig. 4B), which were directly measured up to 110°C. Figure 3B shows the temperature function of ΔH for Ec0VV_6 and the denaturation enthalpy values at the denaturation temperatures of several ionic Ec0VV mutants. This Figure indicates that the ΔH value of Ec0VV is similar to those of Ec0VV_S110R and Ec0VV_6 at each denaturation temperature, but remarkably higher than those of other mutants derived from Ec0VV by the further addition of charged residues.

The thermodynamic parameters of denaturation for *EcCutA1_0SH* mutants at the denaturation temperature (113.2°C) of Ec0VV are listed in Table 2. The ΔG values, estimated using the ΔC_p temperature function obtained from Ec0VV, agreed well with those from Ec0VV_6, around the denaturation temperature of Ec0VV. Figure 4 also shows the temperature functions of ΔG , ΔH , and $T\Delta S$ for Ec0VV and Ec0VV_6 over a larger temperature range (between 280 and 420 K), indicating that ΔG values of Ec0VV_6 are positive over a broad range of temperatures.

Discussion

Forty years ago, Privalov *et al.*^{14,31} developed highly qualified adiabatic differential micro-calorimeters for determining the thermodynamic parameters of protein denaturation. They reported that specific

Figure 3. (A) Temperature dependence of ΔH for hydrophobic *EcCutA1* mutants at pH 9.0. ΔH values (closed circles) of denaturation for *EcCutA1_0SH*, *EcCutA1_0SH_S11V*, *EcCutA1_0SH_E61V*, and *Ec0VV* come from Table 1. The black curves represent the temperature function of ΔH upon denaturation using the temperature function of ΔC_p for *Ec0VV* obtained from Y3 of Supplementary Fig. 4A. The red curve represents $T\Delta S$ of *Ec0VV*. In the case of *Ec0VV*, the parameters A, B, and C of ΔC_p (in $\text{kJ mol}^{-1}\text{K}^{-1}$) in equation (1) were calculated to be 7.61029, -0.26614 , and -8.4434×10^{-4} , respectively. (B) Temperature dependence of ΔH for ionic *Ec0VV* mutants at pH 9.0. ΔH values (closed circles) of denaturation for *EcCutA1* mutants come from Table 1. Black curves represent the temperature function of ΔH upon denaturation, using the temperature function of ΔC_p for *Ec0VV_6* obtained from Y3 of Supplementary Fig. 4B. The red curve represents $T\Delta S$ of *Ec0VV_6*. In the case of *Ec0VV_6*, the parameters A, B, and C of ΔC_p (in $\text{kJ mol}^{-1}\text{K}^{-1}$) in equation (1) were calculated to be 4.22658, -0.29835 , and -10.0757×10^{-4} , respectively.

Table 2. Thermodynamic parameters of denaturation for *EcCutA1_0SH* mutants at the denaturation temperature (113.2°C) of *Ec0VV*. The unit is kJ mol^{-1} . *a and b represent the calculated results using the temperature function of ΔC_p obtained from *Ec0VV* and *Ec0VV_6*, respectively.

characters of amino-acid residues disappear during protein unfolding near 110°C, and that all the observed entropy originates from the increase in conformational freedom of the polypeptide upon unfolding, because the specific ΔH and ΔS of unfolding for several proteins intersect at a single point near 110°C. On the other hand, the thermodynamics of transfer of hydrocarbons to water provides a model for the temperature dependence of the hydrophobic interaction in protein folding. Baldwin¹⁵ examined the solution thermodynamics of several liquid hydrocarbons in water. He found that the extrapolated temperatures at which the transfer ΔS reaches zero, around 112.8°C, were similar for six hydrocarbons. The extrapolated temperature of the transfer ΔH is 22.0°C. This means that at 113°C, the hydrophobic interaction changes from being entropy-driven at 22°C to being enthalpy-driven at 113°C,

Figure 4. Temperature functions of ΔG , ΔH , and $T\Delta S$ for *Ec0VV*, and *Ec0VV_6* between 280 and 420 K. Temperature functions of ΔH and ΔS were obtained using equations (2) and (3), respectively, in which each temperature function of ΔC_p was used for the calculation of *Ec0VV* and *Ec0VV_6*. The green, red, and blue curves represent values of $\Delta G(=\Delta H-T\Delta S)$, ΔH , and $T\Delta S$, respectively. Numbers 1 and 2 represent *Ec0VV_6* and *Ec0VV*, respectively. Open circles with error bars show the ΔH value of each protein at the denaturation temperature, as indicated in the figure.

and the contribution of water to the entropy of protein unfolding (hydrophobic hydration) is removed¹⁵. Regarding these estimations, the heat capacity change (ΔC_p) is assumed to be constant against temperature. Later, Makhatadze and Privalov^{33,34} reported that the temperature at which ΔS is zero approaches 145 °C when the decreasing nature of ΔC_p against temperature is taken into account, because the ΔC_p value of hydrocarbon hydration decreases with increasing temperature.

In this study, the heat capacities of the native states of *Ec0VV* and *Ec0VV_6* could be directly measured by DSC up to 95 and 110 °C, respectively, and the temperature functions of their ΔC_p values were estimated as shown in Supplementary Fig. 4A and Supplementary Fig. 4B, respectively.

Hydrophobic effects strongly contribute to ΔH at temperatures around 100 °C. The temperature function of ΔH of *Ec0VV* is depicted in Fig. 3A. Using the same temperature function of ΔC_p , the ΔH values of *Ec0VV*, *EcCutA1_0SH_S11V*, *EcCutA1_0SH_E61V*, and *EcCutA1_0SH* were estimated to be 1569, 1396, 1340, and 1175 kJ/mol at 113.2 °C, respectively (Table 2). The increase in ΔH (394 kJ/mol) of *Ec0VV* (*EcCutA1_0SH_S11V/E61V*) agrees well with the sum (386 kJ/mol) of the increases in ΔH of *EcCutA1_0SH_S11V* (221 kJ/mol) and *EcCutA1_0SH_E61V* (165 kJ/mol). On the other hand, the $T\Delta S$ values of *Ec0VV* (the red curve in Fig. 3A) were larger than the ΔH value ($=T\Delta S$ at T_d) at each T_d of *EcCutA1_0SH_S11V*, *EcCutA1_0SH_E61V*, and *EcCutA1_0SH*, indicating that *Ec0VV* is entropically unfavorable compared with other proteins. That is, *Ec0VV*, which contains hydrophobic substitutions for hydrophilic residues in the interior of a molecule, is mainly stabilized by the enthalpic gain upon substitutions, but is partly destabilized by the entropic loss, probably due to the disruption of the hydrophilic solvation in the denatured state upon substitutions. These results at high temperatures around 100 °C are contrary to the well-accepted belief that the entropic gain from hydrophobic solvation can account for the stabilization effect of hydrophobic substitutions at lower temperatures¹⁵. Whereas, the estimations from the hydration of amino acids³⁴ are generally consistent with our results. This is the first experimental evidence pertaining to the hydrophobic effects on protein stability, which is obtained by direct measurement at temperatures around 100 °C.

***Ec0VV_6* substituted with six charged residues is stabilized by both enthalpic and entropic effects around 137 °C.** Below 100 °C, the ion–ion interaction (salt bridge) is driven entirely by entropic effects due to the release of water strongly bound to the ions of charged residues^{35–37}. The proteins substituted with single charged residues, *Ec0VV_H72K*, *Ec0VV_S82K*, *Ec0VV_Q87K*, and *Ec0VV_T88R*, are stabilized by electrostatic interactions (Supplementary Fig. 3). The ΔH values of all of these proteins were drastically decreased relative to ΔH at each corresponding temperature on the temperature function of *Ec0VV_6* (Fig. 3B). Because the changes in ΔH upon these mutations are unfavorable for folding, the observed improvements in stability were caused by entropic effects due to the release of water at the charged residues that we introduced (electrostatic solvation). The thermodynamic analyses also clearly confirmed stabilization resulted from entropic effects (Table 2). The other single mutants, *Ec0VV_A39D* and *Ec0VV_S48K*, whose mutation sites were located in the interior of the molecule (Table 3), demonstrated drastically decreased T_d and ΔH values. However, a double mutant containing both of these single mutants, *Ec0VV_A39D/S48K*, in which Asp39 forms a strong salt bridge with Lys48, was stabilized by an increase in ΔH relative to the single mutants (Fig. 3B), probably due to Coulomb's force resulting from

Mutants	Residues	All atoms			Charged atoms			location

Table 3. Burial rates of target residues of *Ec0VV* mutants*. *The burial rates (%) were estimated from the average of ASA values for nine structures during 40 ns MD at 300 K (in preparation).

salt bridge formation. A similar result was obtained in the other double mutant, *Ec0VV_T17K/S48D* (Fig. 3B). The double mutant *Ec0VV_Q87K/T88R* was also stabilized by an increase in ΔH relative to *Ec0VV_Q87K* and *Ec0VV_T88R*. Because this double mutant does not have additional salt bridges, two individual thermo-stabilizations might work synergistically at around 120 °C to promote the desolvation of the ionic residues introduced, thereby reducing both the enthalpic loss and the entropic gain that are mutually attributed to the electrostatic solvation. In addition, the increase in ΔH in this double-ion mutant might have been caused by a hydrophobic interaction due to the alkyl groups of Lys87 and Arg88.

Ec0VV_6, with six additional charged residues, was stabilized by an increase in the ΔH value relative to each of the six original ionic mutants (Fig. 3B). The increase in ΔH might indicate that hydrophobic effects due to the alkyl groups of Lys or Arg and Coulomb's force still function effectively at these high temperatures. According to Coulomb's law, the strength of an electrical interaction is inversely proportional to the dielectric constant. The dielectric constant of water drops from 80 at 0 °C to 55 at 100 °C³⁸. Furthermore, Elcock³⁹ found that increasing temperature decreases the electrostatic desolvation penalty incurred in forming a salt bridge, leading to an increase in salt bridge stabilization from his continuum solvation model⁴⁰. The increase in ΔH of *Ec0VV_6* might result mainly from the high degree of desolvation of the ionic residues in the denatured state at around 137 °C, in addition to the other effects described above.

The temperature dependence of ΔH for *Ec0VV_6* has an intersection near T_d (113 °C) of *Ec0VV*, as shown in Fig. 4, suggesting that the contribution of ΔH to the stability of *Ec0VV_6* with additional 6 charged residues becomes favorable in the temperature region above 113 °C, compared with those of *Ec0VV*. Furthermore, Fig. 4 shows that the increase in ΔG of *Ec0VV_6* results largely from the decrease in ΔS of *Ec0VV_6* when compared with the template *Ec0VV* at temperatures below 113 °C. That is, the stabilization due to ionic mutations results mainly from both the enthalpic gain from ion-ion interactions in the native state and the entropic gain from the water release of ionic residues in the denatured state at temperatures over 113 °C.

A mutant, *Ec0VV_S110R*, whose substitution position is located in the C-terminus of α -helix and almost buried (Table 3), was stabilized by an increase in ΔH (Fig. 3B). In this case, due to local conformations, the decrease in ΔH due to water release might be suppressed by the effects of other stabilizing factors.

Conclusion

The rational design of hyper-thermostable proteins may be possible through the introduction of multiple salt bridges at high temperatures over 113 °C that can be reached through a preceding stabilization by hydrophobic substitutions.

Materials and Methods

Mutagenesis, expression, and purification of CutA1 mutants from *E. coli*. The mutagenesis, expression, and purification of CutA1 mutants from *E. coli* were performed as described³⁰ with minor modifications. The homogeneity and identity of the purified samples were assessed using SDS-PAGE. The protein concentration was estimated from the absorbance at 280 nm, assuming $E^{1\text{cm}}_{1\%} = 14.96$, based on the number of aromatic amino acids⁴¹.

Differential scanning calorimetry (DSC) experiments. To measure the changes in stability due to mutations, DSC was performed using a scan rate of 60 °C/h on a VP-capillary DSC platform (Microcal, USA) for temperatures up to 130 °C at pressures below 60 psi, or a Nano-DSC 6300Y microcalorimeter (TA Instruments, USA) for higher temperatures up to 160 °C at a pressure of 88 psi. Protein concentrations were around 0.6 mg/ml in a 50 mM glycine buffer at pH 9.0 containing 2 mM EDTA or a 50 mM

glycine buffer at pH 2.0–3.5. All samples were dialyzed against the buffers overnight at 4°C and then filtered through a membrane with 0.22- μm pores. The denaturation temperature (T_d) is the temperature at which the area of the denaturation enthalpy (ΔH) is 0.5. The T_d and ΔH values in this study represent the averages for at least six experiments.

To measure the heat capacity of mutant proteins in their native states, the protein concentrations were adjusted to around 2.0 mg/ml in a 50 mM glycine buffer at pH 9.0. Two different scan rates, 60 and 200°C/h, were used. Each experiment comprised six cycles of reheating to the pre-denaturation temperatures: 95°C and 110°C for *Ec0VV* and *Ec0VV_6*, respectively. The partial specific volumes for the calculation of heat capacity were estimated from the amino-acid composition of each mutant protein⁴².
