THz wave has been increasingly applied in engineering practice. One of its outstanding advantages is the penetrability through certain optically opaque materials, whose interior properties could be therefore obtained. In this report, we develop an experimental method to determine the plane stress state of optically opaque materials based on the stress-optical law using terahertz time-domain spectroscopy (THz-TDS). In this method, two polarizers are combined into the conventional THz-TDS system to sense and adjust the polarization state of THz waves and a theoretical model is established to describe the relationship between phase delay of the received THz wave and the plane stress applied on the specimen. Three stress parameters that represent the plane stress state are finally determined through an error function of THz wave phase-delay. Experiments were conducted on polytetrafluoroethylene (PTFE) specimen and a reasonably good agreement was found with measurement using traditional strain gauges. The presented results validate the effectiveness of the proposed method. The proposed method could be further used in nondestructive tests for a wide range of optically opaque materials.

Terahertz (THz) wave has obtained wide applications in various fields since powerful sources were developed^{1,2}. As a key spectral analysis technique in the THz waveband, THz-TDS obtained many valuable applications in characterization of semiconductors and biological materials^{3–6}, 2D and tomographic imaging^{7,8}, and geometric parameter measurement⁹. One outstanding feature of the THz wave is its high transmission ability through most optically opaque materials^{10–12}, so that it can be used to determine and analyze the internal properties of these materials.

Stress state is important interior information of optically opaque materials as a response to external mechanical loadings. Recently, researchers reported their progresses in studying the stress-optical effect in THz regime^{13–17}. In order to clarify the subtle differences among these works, a brief introduction to the stress-optical law is presented. The stress-optical law states that mechanical stress makes an originally isotropic material become optically anisotropic and the optical axes of the stress induced birefringence are aligned with the stress principle axes. If the specimen is under the plane stress state, the refractive index variations can be expressed using the stress parameters according to the following equation¹⁸

$$\Delta N_1 = A\sigma_1 + B\sigma_2, \quad (1)$$

$$\Delta N_2 = A\sigma_2 + B\sigma_1. \quad (2)$$

where ΔN_1 and ΔN_2 are the variations in material refractive index along the directions of the principle stresses, and A and B are called stress-optical coefficients. For a plane stressed specimen, three parameters, including σ_1 , σ_2 and θ , are needed to describe its stress state. Here, σ_1 and σ_2 are the so-called principle stresses, while θ is the angle between the x -axis and σ_1 . Apparently, the plane stress state can be determined if ΔN_1 and ΔN_2 , and θ are obtained in advance. Subtract Eq. (2) from Eq. (1), it can be obtained that

$$\Delta N_1 - \Delta N_2 = (A - B)(\sigma_1 - \sigma_2) = C(\sigma_1 - \sigma_2), \quad (3)$$

where parameter C is the stress-optical coefficient used in the photoelasticity and $C = A - B$.

To the best knowledge of the authors, the research work on stress measurement using THz radiation was launched in 2004 by Tsuguhiro¹³. An experimental system was built based on back-ward wave oscillator to carry out experiments on a polyethylene specimen. The difference between ΔN_1 and ΔN_2 was measured and the stress-optic coefficient C was obtained. By using a movable loading stage, the intensity distribution of the transmitted THz wave was also obtained when the polarizer and analyzer formed a cross-Nicol system. However, the stress information was not extracted from the intensity distribution. Ebara *et al.* constructed a polarized sensitive TDS system that could detect small birefringence¹⁴. Using this highly sensitive THz-TDS system, they measured the stress-caused birefringence, i.e. $\Delta N_1 - \Delta N_2$, when a uniaxial stress was applied on a specimen. According to their experimental result, the stress-optic coefficient C of PTFE was determined. Pfleger *et al.* measured the birefringence and the optical axes orientation of the LiNbO₃ crystal¹⁵. But, the presented method can not be directly used for stress measurement due to relatively small magnitude of the stress induced-birefringence. Recently, we obtained the relationship between the uniaxial tensile stress and the refractive index change ΔN_1 and the stress-optical coefficient A of PTFE^{16,17}.

In the above works, the stress-caused refractive index changes have been experimentally measured as $\Delta N_1 - \Delta N_2$ or ΔN_1 . Based the above results, it is straight forward to measure a uniaxial stress, in which there is only one stress parameter to be measured. However, it is impossible to determine a plane stress state, in which there are three unknown parameters to be determined. Although great effort was made to characterizing birefringence in THz regime^{19,20}, no work succeeded on determination of the plane stress state using THz wave.

In this report, we develop an experimental method to determine the plane stress state in optically opaque materials using an improved THz-TDS system. An experimental principle is also established with respect to the improved THz-TDS system. The proposed method is experimentally validated and the plane stress states of PTFE specimens were obtained.

Methods

Compared with the conventional THz-TDS, the system used for plane stress state measurement is improved by integrating two polarizers to sense and adjust the polarization state of the THz waves. Figure 1 schematically shows the orientations of the two added polarizers and the stress components. In the improved THz-TDS system, the emitted THz wave is horizontally polarized. Suppose the phase and the amplitude of the emitted THz wave are 0 and 1 respectively, the electric field E_0 can be expressed using the Jones vector as

$$E_0 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}. \quad (4)$$

As the incident THz radiation transmits through the specimen that is loaded by a plane stress, it is divided into two polarized radiation along the two principal stress directions, which are perpendicular to each other. As illustrated in Fig. 1, the THz wave subsequently passes Polarizer I, the specimen, and Polarizer II. The received THz wave can therefore be expressed as

$$E_1 = P_0 \cdot Q'_\varphi \cdot J_\theta \cdot Q_\varphi \cdot E_0, \quad (5)$$

where

$$Q_\varphi = \begin{bmatrix} \cos^2 \varphi & \sin \varphi \cos \varphi \\ \sin \varphi \cos \varphi & \sin^2 \varphi \end{bmatrix}, \quad (6)$$

$$J_{\theta} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \cdot \begin{bmatrix} \exp(i\delta_1) & 0 \\ 0 & \exp(i\delta_2) \end{bmatrix} \cdot \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix}, \quad (7)$$

$$Q'_{\varphi} = \begin{bmatrix} \cos^2 \varphi' & \sin \varphi' \cos \varphi' \\ \sin \varphi' \cos \varphi' & \sin^2 \varphi' \end{bmatrix}, \quad (8)$$

and

$$P_0 = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}. \quad (9)$$

In Eq. (5), Q_{φ} and Q'_{φ} are the Jones matrix of the two polarizers, φ and φ' are the angles between Polarizer I, II and the horizontal direction respectively, J_{θ} is the Jones matrix of the loaded specimen, θ is the angle between the first principal stress and the horizontal direction, δ_1 and δ_2 are the stress-caused phase delays of the two polarized components along the directions of σ_1 and σ_2 , and P_0 is used to extract the horizontally polarized component because the detector in the TDS system can only detect that component of the THz radiation. Equation (5) can be simplified as

$$E_1 = \begin{bmatrix} T e^{i\alpha} \\ 0 \end{bmatrix} = \begin{bmatrix} R \cos \alpha + iI \sin \alpha \\ 0 \end{bmatrix}. \quad (10)$$

where $T e^{i\alpha}$ represents the received THz wave. R and I are the real and the imaginary parts, and α is the phase delay of the received THz wave caused by the applied stress. After simplification, the phase delay α can be expressed as

$$\tan \alpha = \frac{P \sin \delta_1 + Q \sin \delta_2}{P \cos \delta_1 + Q \cos \delta_2} \quad (11)$$

where

$$P = \cos \varphi \cdot \cos \varphi' \cdot \cos(\varphi' - \theta) \cdot \cos(\varphi - \theta). \quad (12)$$

$$Q = \cos \varphi \cdot \cos \varphi' \cdot \sin(\varphi' - \theta) \cdot \sin(\varphi - \theta). \quad (13)$$

Speaking specifically, the phase delays, δ_1 and δ_2 , are caused by the stress-optical effect and the Poisson effect when stresses are loaded on the specimen and can be calculated using the following equations as

$$\delta_1 = \frac{2\pi df}{c} \left[\left(A - \frac{\mu(N_0 - 1)}{E} \right) \sigma_1 + \left(B - \frac{\mu(N_0 - 1)}{E} \right) \sigma_2 \right], \quad (14)$$

$$\delta_2 = \frac{2\pi df}{c} \left[\left(A - \frac{\mu(N_0 - 1)}{E} \right) \sigma_2 + \left(B - \frac{\mu(N_0 - 1)}{E} \right) \sigma_1 \right]. \quad (15)$$

where f is the frequency of the THz radiation, c is the speed of light in air, d is the original thickness of the specimen, N_0 , E and μ are the initial refractive index, the elastic modulus and the Poisson ratio of the specimen, respectively. Therefore, the relationship between the phase delay α of the captured THz wave and the applied plane stress state can be determined by combining Eqs (11, 14 and 15).

To measure the three stress parameters, the two polarizers are placed at three different orientations and the phase delay data between free and loaded conditions are captured. Since the experimentally captured THz signals are broadband, the phase delay at the n th frequency component f_n for the k th polarizer orientation is denoted as α_n^k . An error function of the phase delay is thereby defined as:

$$e(\sigma_1, \sigma_2, \theta) = \sum_{k=1}^3 \sum_{n=1}^N [\bar{\alpha}_n^k(\sigma_1, \sigma_2, \theta) - \alpha_n^k]^2, \quad (16)$$

where $\bar{\alpha}_n^k(\sigma_1, \sigma_2, \theta)$ is the phase delay calculated using Eqs (11, 14 and 15) for any arbitrary set of $(\sigma_1, \sigma_2, \theta)$. The Newton-Raphson method is used to obtain the minimum of this error function. The specific value of $(\sigma_1, \sigma_2, \theta)$ that minimizes the error function is regarded as the real plane stress state undergone by the specimen.

Experiments. Experiments were conducted on a dumbbell-shaped PTFE sheet specimen. The specimen was fixed on a mechanical loading device that provided the uniaxial tensile loading. The phase spectra of the free and loaded specimen were measured. Meanwhile, strain gauges were glued on the specimen surface to measure the tensile strain, which was used for stress calculation for comparison. Table 1 presents the geometric and physical parameters of the PTFE specimen.

In the improved THz-TDS system, two wired-grid polarizers were added to the standard THz-TDS system, where a femtosecond laser with 88 MHz repetition rate, 26 fs pulse width, and 800 nm wavelength was used as the pump source with a 10 mW average power for both the THz transmitter and receiver. The THz wave was generated and detected by shorting the dipole-type photoconductive antenna gap. Because the refractive index change to be measured would be very small, high signal stability is critical for experimental measurement. In order to

keep the THz signal stable, humidity is controlled below 2% by mixing dry air into the sealed chamber during the measurement. The highly reliable frequency range of the THz-TDS system is 0.4~1.80 THz.

Results

Stress-optical coefficients measurement. The two stress-optical coefficients A and B are imperative in stress state calculation and can only be obtained through experiments. In order to measure coefficient A of the PTFE specimen, the loading device was placed horizontally so that a horizontal uniaxial stress was applied on the specimen. The polarization directions of the two polarizers were also set horizontal. In this case, θ , φ , φ' and σ_2 are all equal to zero and σ_1 is equal to the horizontally applied stress. Thus, stress-optical coefficient A can be obtained from Eqs (11–14) as

$$A = \frac{c}{2\pi d} \cdot \frac{\alpha}{f} \cdot \frac{1}{\sigma_h} + \frac{\mu N_0}{E}, \quad (17)$$

where σ_h is the applied horizontal uniaxial stress and α/f represents the slope of phase delay with respect to frequency when a stress is applied on the specimen. Figure 2a shows five phase delay vs. frequency curves under different horizontal stresses. The stress-optical coefficient A is thus obtained as $2.03 \times 10^{-9} \text{ Pa}^{-1}$ using Eq. (17).

The stress-optical coefficient B was similarly obtained, except that the loading device was vertically placed to obtain a vertical stress. The two polarizers were kept horizontal. In this case, $\theta = 90^\circ$, $\varphi = 0$, $\varphi' = 0$, $\sigma_2 = 0$, and σ_1 equals to the vertically applied stress. The coefficient B could be obtained from Eqs (11–13 and 15) as

$$B = \frac{c}{2\pi d} \cdot \frac{\alpha}{f} \cdot \frac{1}{\sigma_v} + \frac{\mu N_0}{E}, \quad (18)$$

where σ_v is the vertically applied uniaxial stress. Figure 2b shows the phase delay vs. frequency when different vertical stresses were applied. The stress-optical coefficient B is then obtained as $2.63 \times 10^{-9} \text{ Pa}^{-1}$ according to Eq. (18).

Plane stress state measurement. The plane stress state of the PTFE specimen was measured under four different loadings. In the first two experiments, horizontal loadings were applied on the specimen, while vertical loading were applied in the other two experiments. The applied stress states are obtained by strain gauge and listed in Table 2 for comparison. The specimen is supposed to be under general plane stress states. As stated previously, in order to obtain specimen plane stress state that is actually represented by the three stress parameters, σ_1 , σ_2 and θ , the phase delay of the captured THz waves needs to be measured at three different orientation settings of the two polarizers. The three orientation settings in the experiment were: 1) $\varphi = 0$, $\varphi' = 0$; 2) $\varphi = 45^\circ$, $\varphi' = 45^\circ$; and 3) $\varphi = 60^\circ$, $\varphi' = -60^\circ$, respectively. For each orientation setting, the THz wave was captured for both free and loading conditions. The phase delays at different frequency components were obtained by Fourier transform and served as α_n^k in Eq. (16).

Table 2. Measurement Results of the Stress State. **Figure 3.** Distribution of the error function $e(\sigma_1, \sigma_2)$ when $\theta = 13^\circ$. **Figure 4.** Phase delays of the first experimental measurement and theoretical simulation.

The measured plane stress states using the proposed THz method are presented in Table 2. The stress states are represented by the stress parameters that make the error function minimum under each loading condition. For the first loading condition, the plane stress state obtained by THz-TDS is $\sigma_1 = 1.7$ MPa, $\sigma_2 = -0.1$ MPa, and $\theta = 13^\circ$. Figure 3 shows the distribution of the error function in the $\sigma_1 - \sigma_2$ plane when $\theta = 13^\circ$. A well-shaped minimum is shown in the figure. Thus, it is reliable to achieve the minimum by the Newton-Raphson scheme. Figure 4 compares the theoretical and experimental phase delays at the frequency domain under the first plane stress state. Good agreements are indicated between the experimental results and the theoretical calculation for the three polarizer orientation settings. The error function distributions and phase delay curves of the other three measurements are provided in Supplementary Figures.

Discussion

Comparison between the plane stress states obtained by the proposed method and the results by the strain gauges indicates a relatively apparent difference in the stress parameters σ_2 and θ . Several factors may account for the difference. One possible reason may be the nonlinear mechanical property of PTFE. It could induce some inevitable error when strain gauges are used to measure the stress state. It is assumed in this report that free specimens are optically isotropic. But actually residual birefringence may exist in unstressed specimens. This may be another influencing factor. Stability of the THz signal also affects the precision of stress measurement. Another factor may

be the relatively low extinction ratios of the metallic wire-grid THz polarizers used in the THz-TDS system. Thus, the penetrated THz waves would not be perfectly polarized. Therefore, further efforts should be contributed to improving accuracy and stability of the proposed method.

It may also be noticed that in the proposed method only the phase data of the received signal is used in stress determination, while the magnitude information is ignored, which is different or contradictory to conventional THz wave applications. This is because the amplitude data of our THz-TDS system is not stable enough. The instability of the amplitude data makes it impractical to achieve accurate measurement on stress states.

Using the proposed method, THz waves can not only be used to find interior flaw in materials, but also to determine the stress distribution when material under mechanical loading. Some flaws may be too small to be detected, but they induce obviously singular stress distributions that could be identified by stress measurement. Thus, the proposed stress measurement method here is possibly developed to be a prospective non-destructive testing method in future.
