The soluble  $\gamma$ c protein ( $s\gamma$ c) is a naturally occurring splice isoform of the  $\gamma$ c cytokine receptor that is produced by activated T cells and inhibits  $\gamma$ c cytokine signaling. Here we show that  $s\gamma$ c expression is also highly upregulated in immature CD4<sup>+</sup>CD8<sup>+</sup> thymocytes but then downregulated in mature thymocytes. These results indicate a developmentally controlled mechanism for  $s\gamma$ c expression and suggest a potential role for  $s\gamma$ c in regulating T cell development in the thymus. Indeed,  $s\gamma$ c overexpression resulted in significantly reduced thymocyte numbers and diminished expansion of immature thymocytes, concordant to its role in suppressing signaling by IL-7, a critical  $\gamma$ c cytokine in early thymopoiesis. Notably,  $s\gamma$ c overexpression also impaired generation of *i*NKT cells, resulting in reduced *i*NKT cell percentages and numbers in the thymus. *i*NKT cell development requires IL-15, and we found that  $s\gamma$ c interfered with IL-15 signaling to suppress *i*NKT cell generation in the thymus. Thus,  $s\gamma$ c represents a new mechanism to control cytokine availability during T cell development that constrains mature T cell production and specifically *i*NKT cell generation in the thymus.

Cytokines of the  $\gamma$ c family play critical roles in T cell development in the thymus<sup>1,2</sup>. Among others, IL-7 is essential for thymopoiesis<sup>2,3</sup>, IL-2 is necessary for Foxp3<sup>+</sup> Treg cell development<sup>4,5</sup>, and IL-15 is required for the development of invariant NKT (*i*NKT) cells in the thymus<sup>6,7</sup>. Notably,  $\gamma$ c cytokine responsiveness is mostly acquired during or after initiation of lineage-specification during thymocyte development. As such, pre-selection CD4<sup>+</sup>CD8<sup>+</sup> double-positive (DP) thymocytes are unresponsive to IL-7<sup>8,9</sup>, and IL-7 responsiveness is acquired upon cessation of positive selection signals in post-selection CD4 or CD8 single-positive (SP) thymocytes<sup>3,10,11</sup>. DP thymocytes are also unresponsive to IL-2, and IL-2 responsiveness in CD4 thymocytes is only acquired by strong TCR engagements that also upregulate expression of the transcription factor Foxp3<sup>12,13</sup>. We and others have previously proposed that such  $\gamma$ c unresponsiveness in DP thymocytes is achieved through multiple redundant mechanisms<sup>9,10,14</sup>, and that prevention of pro-survival  $\gamma$ c cytokine signaling is critical to ensure selection of self-peptide/MHC-specific, immunocompetent T cells<sup>10,15,16</sup>.

The ability to respond to a specific  $\gamma$ c cytokine depends on surface cytokine receptor expression. IL-7R $\alpha$  expression is silenced in pre-selection DP thymocytes but induced upon TCR-mediated positive selection, which correlates with the inability of IL-7 signaling by DP cells<sup>17–19</sup>. Moreover, IL-2 receptor expression is absent in DP and most CD4SP thymocytes, but upregulated in Foxp3<sup>+</sup> Treg precursor cells which depend on IL-2 for survival<sup>13</sup>. IL-2 receptor expression is also critical for generation of *i*NKT cells who utilize IL-2R $\beta$  to be signaled by IL-15, a critical survival and differentiation cytokine for *i*NKT cells<sup>7,20,21</sup>. The failure to express cytokine receptors in a stage-specific manner is detrimental for thymocyte development and lineage differentiation<sup>22,23</sup>. Thus, understanding the molecular mechanisms that control expression of  $\gamma$ c family cytokine receptors during differentiation of distinct thymocyte subsets is an important issue in T cell biology. Interestingly, and in contrast to the cytokine-proprietary receptors, the regulatory mechanism of  $\gamma$ c expression has remained largely unmapped.

$\gamma_c$  is expressed on immature CD4, CD8 double-negative (DN) thymocytes for survival and proliferation, and  $\gamma_c$  expression is also upregulated upon positive selection to mediate lineage choice and effector cell differentiation<sup>19</sup>. Importantly,  $\gamma_c$  expression is downregulated on immature DP cells, presumably to suppress aberrant  $\gamma_c$  cytokine signaling that could provide pro-survival effects on pre-selection thymocytes<sup>19</sup>. However, the molecular pathway that suppresses  $\gamma_c$  expression on DP cells remains still veiled.

We have previously identified alternative splicing of  $\gamma_c$  pre-mRNA as a new mechanism to reduce surface  $\gamma_c$  protein expression<sup>24</sup>. The  $\gamma_c$  gene is encoded in 8 exons, and exon 6 encodes the entire transmembrane domain<sup>25</sup>. While the full-length  $\gamma_c$  protein is a transmembrane protein, the new splice isoform lacks exon 6 and thus the transmembrane region, making it a soluble secreted protein. Because the soluble form of  $\gamma_c$  ( $s\gamma_c$ ) is generated at the expense of membrane  $\gamma_c$  protein expression,  $s\gamma_c$  expression inversely correlates with the amount of surface  $\gamma_c$  expression. Therefore,  $s\gamma_c$  expression represents a novel mechanism to suppress  $\gamma_c$  expression on cell surface.

In the present study, we now identify DP thymocytes as a major source of  $s\gamma_c$  and we propose that alternative splicing into  $s\gamma_c$  could promote establishing the low level of surface  $\gamma_c$  on pre-selection DP thymocytes. Moreover, because  $s\gamma_c$  proteins suppress signaling of  $\gamma_c$  cytokines, such as IL-2 and IL-7<sup>24</sup>,  $s\gamma_c$  production by DP thymocytes would create an overall suppressive milieu for  $\gamma_c$  cytokine signaling in the thymus. In fact, we found that  $s\gamma_c$  overexpression resulted in significantly diminished percentages and numbers of thymic *i*NKT cells, which are critically dependent on IL-15 signaling for their development and differentiation<sup>6,7,20,21</sup>. Specifically, increased  $s\gamma_c$  expression resulted in the loss of HSA<sup>lo</sup> mature *i*NKT cells, as it interfered with upregulation of anti-apoptotic Bcl-2 expression and induced increased cell death. Collectively, these data demonstrate a previously unappreciated role for  $s\gamma_c$  in downregulating surface  $\gamma_c$  expression and also in dampening  $\gamma_c$  cytokine signaling in thymocytes, which can inhibit the generation and differentiation of specific T cell subsets in the thymus.

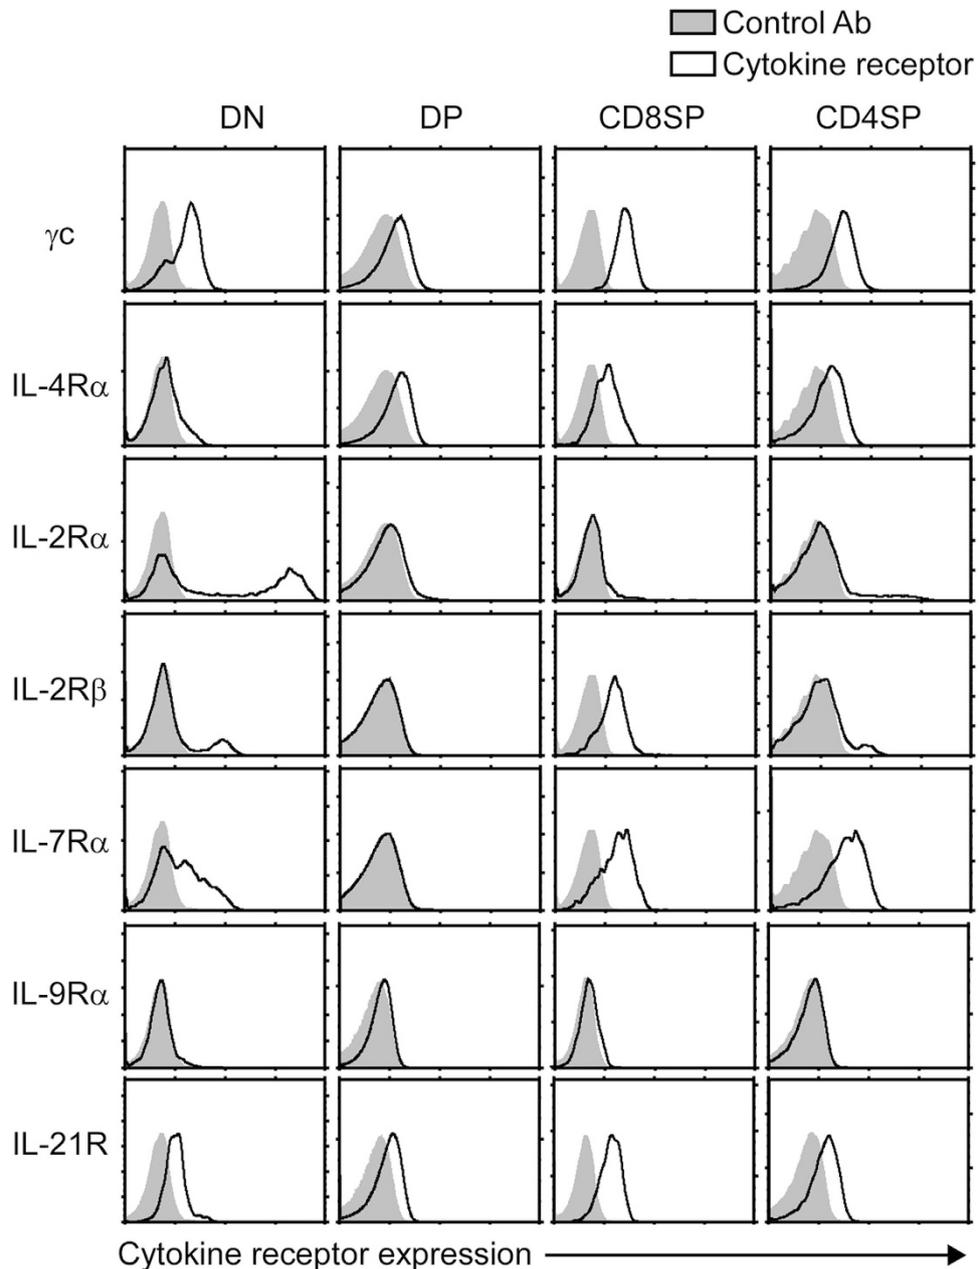

## Results

**$\gamma_c$  family cytokine receptor expression on thymocytes.** Surface staining for  $\gamma_c$  family cytokine receptors revealed distinct and stage-specific expression of individual cytokine receptors (Fig. 1). Most  $\gamma_c$  family cytokine receptors were found on both CD4 and CD8 single positive (SP) thymocytes but absent on immature DP thymocytes. IL-4R $\alpha$ , IL-21R and  $\gamma_c$  differed as they were also expressed on DP cells. Consequently, DP thymocytes would be unable to respond to IL-7, but they are equipped with IL-4 and IL-21 responsiveness. Importantly, while DP cells did express  $\gamma_c$ , the amount of surface  $\gamma_c$  was markedly lower compared to that on immature DN or mature SP thymocytes (Fig. 1). These results indicated and confirmed that  $\gamma_c$  expression is a developmentally controlled event that is specifically suppressed on pre-selection DP cells<sup>19</sup>. Reduced  $\gamma_c$  expression presumably helps avoiding signaling by pro-survival  $\gamma_c$  cytokines which could interfere with TCR-induced positive selection as previously suggested<sup>16</sup>.

To correlate  $\gamma_c$  expression with positive selection, next, we analyzed surface expression of  $\gamma_c$  and IL-7R $\alpha$  on HSA<sup>hi</sup>TCR $\beta$ <sup>lo</sup> pre-selection (gate I) and HSA<sup>lo</sup>TCR $\beta$ <sup>hi</sup> post-selection thymocytes (gate II) (Fig. 2a). Expression of IL-7R $\alpha$  and  $\gamma_c$  was low on gate I immature DP thymocytes but upregulated on gate II mature SP cells, which illustrated developmental control of cytokine receptor expression in thymocytes. The molecular mechanism that downregulates  $\gamma_c$  expression on DP thymocytes is not known. However, we previously reported a post-transcriptional mechanism that can downregulate surface  $\gamma_c$  expression<sup>24</sup>. Specifically, we found that alternative splicing of  $\gamma_c$  transcripts produced a soluble form of  $\gamma_c$  ( $s\gamma_c$ ) that was generated at the expense of membrane  $\gamma_c$  ( $m\gamma_c$ ) protein expression<sup>24</sup>. Thus, increase in  $s\gamma_c$  expression conversely results in reduced surface  $\gamma_c$  expression. Interestingly, here we found that DP thymocytes expressed markedly higher levels of  $s\gamma_c$  transcripts than mature SP thymocytes (Fig. 2b right), and that increased  $s\gamma_c$  expression inversely correlated with decreased  $m\gamma_c$  protein expression in the same cells (Fig. 2b). These data suggest that alternative splicing of  $\gamma_c$  mRNA might contribute to downregulation of surface  $\gamma_c$  expression on DP thymocytes. Moreover, DP cells comprise up to 90% of total thymocytes so that they are a major source of  $s\gamma_c$  proteins, and thus render the thymus into an  $s\gamma_c$ -rich environment. However, if  $s\gamma_c$  plays a role in thymocyte differentiation is not known.

**$s\gamma_c$  overexpression impairs thymocyte development.** To interrogate  $s\gamma_c$ 's effect on T cell development, we analyzed thymocytes in  $s\gamma_c$  transgenic mice ( $s\gamma_c$ Tg)<sup>24</sup>. To generate  $s\gamma_c$ Tg mice, a murine  $s\gamma_c$  cDNA was placed under the control of a human CD2 mini-cassette so that  $s\gamma_c$  is overexpressed in all T lineage cells. Increased  $s\gamma_c$  expression significantly reduced total thymocyte numbers, and we observed an inverse correlation of  $s\gamma_c$  expression and total thymocyte numbers in WT,  $s\gamma_c$  medium (M) and  $s\gamma_c$  high (H) expresser transgenes (Fig. 3a). All further experiments in this study were done with the  $s\gamma_c$  high expresser line. Assessing thymocyte profiles of  $s\gamma_c$ Tg mice did not reveal any significant changes in TCR $\beta$ <sup>hi</sup> mature T cell generation (Fig. 3b) or in CD4/CD8 lineage commitment (Fig. 3c left). However, we did find a significant increase in DN cell frequency (Fig. 3c right), suggesting a developmental defect in DN to DP cell transition, which would also explain the reduction in thymocyte numbers in  $s\gamma_c$ Tg mice (Fig. 3d)<sup>26</sup>.

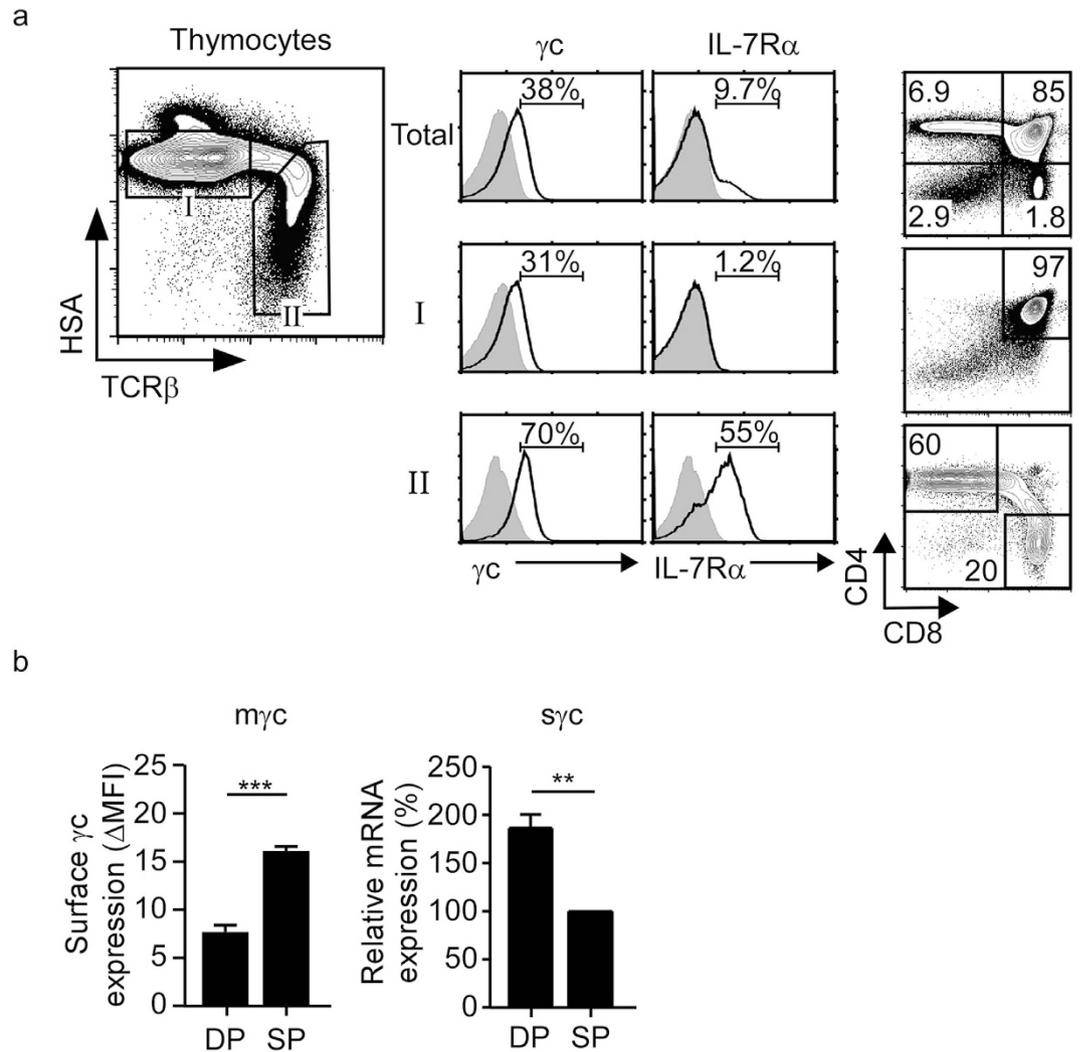

To directly address this point, we examined surface CD44 and CD25 expression in lineage marker negative DN thymocytes and determined DN1-DN4 differentiation in  $s\gamma_c$ Tg and WT thymocytes (Fig. 4a)<sup>27</sup>. Contrary to our expectation, however, we did not find any significant differences in DN1-4 subset frequencies between WT and  $s\gamma_c$ Tg mice. We also did not find any significant difference in Ki-67 expression in individual DN subsets (Fig. 4b), suggesting that the proliferative potential of  $s\gamma_c$ Tg DN cells did not differ from WT thymocytes. Finally, to examine the possibility that increased cell death of DN thymocytes would account for reduced cell numbers, we assessed caspase-3 activity and intracellular Bcl-2 contents in  $s\gamma_c$ Tg DN thymocytes (Fig. 4c). Decreased Bcl-2 expression is associated with increased susceptibility to apoptosis, and elevated caspase-3 activity is indicative of increased cell death<sup>28,29</sup>. However, we did not find any differences in their expression either between  $s\gamma_c$ Tg and WT DN thymocytes (Fig. 4c).

**Figure 1. Cell surface expression of  $\gamma_c$  family cytokine receptors on thymocytes.** Expression of the indicated cytokine receptors were assessed on thymocyte subpopulations. Data are representative of 5 independent experiments.

Notably, DP thymocytes in  $s\gamma_c$ Tg mice had been previously reported to contain increased percentages of CD25-positive cells<sup>24</sup>. Also, surface CD25 expression is diluted during the proliferative burst of DN to DP transition<sup>30</sup>. Thus, these results collectively suggested that reduced thymocyte numbers and increased DN cell percentages are results of reduced cell proliferation during DN to DP cell transition and not due to a developmental arrest at DN2/DN3 stage of T cell development.

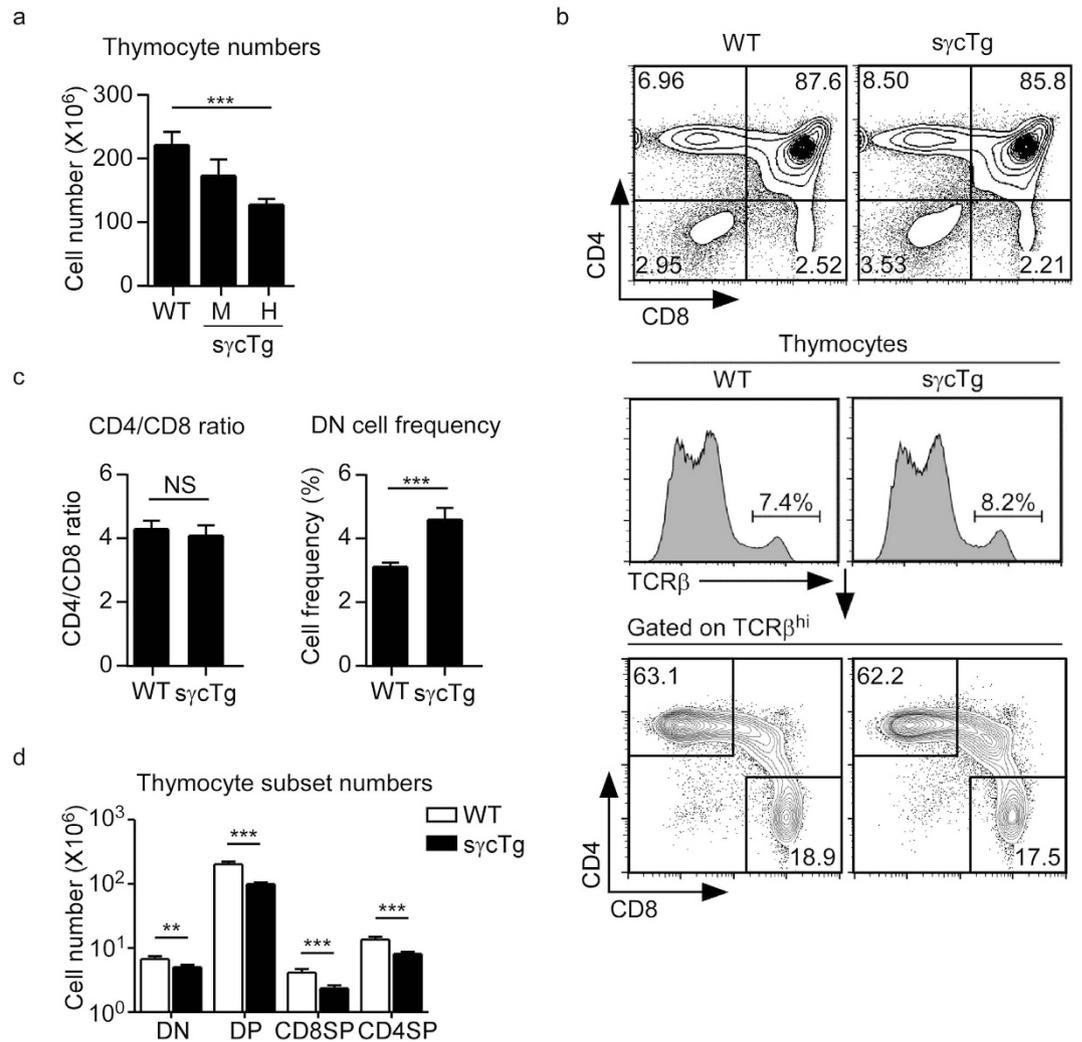

**Thymic development of  $\gamma\delta$  T cells and Foxp3<sup>+</sup> Treg cells in  $s\gamma_c$ Tg mice.** To further assess the impact of increased  $s\gamma_c$  expression, next, we analyzed generation of individual thymic T cell subsets. We first assessed  $\gamma\delta$  T cell generation in the thymus and found it unaffected in  $s\gamma_c$ Tg mice. Thymic  $\gamma\delta$  T cell numbers did not differ between WT and  $s\gamma_c$ Tg mice, and because overall thymocyte numbers were decreased in  $s\gamma_c$ Tg mice, this translated into increased percentages of  $\gamma\delta$  T cells in the thymus (Fig. 5a). Next, we examined generation of Foxp3<sup>+</sup> T regulatory (Treg) cells in  $s\gamma_c$ Tg thymocytes, and found a significant decrease in Foxp3<sup>+</sup>CD25<sup>+</sup> CD4SP Treg cell numbers (Fig. 5b). However, we did not find a decrease in Foxp3<sup>+</sup>CD25<sup>+</sup> cell percentages among CD4SP thymocytes (Fig. 5b), which indicated that reduced Foxp3<sup>+</sup> Treg cell number is due to an overall impairment in thymopoiesis and not because of a specific defect in thymic Treg cell generation.

**Figure 2. Immature DP thymocytes express low levels of membrane  $\gamma c$  but high levels of soluble  $\gamma c$  proteins.** (a) Stage-specific expression of cell surface IL-7R $\alpha$  and  $\gamma c$  during thymocyte development. Contour plot shows HSA and TCR $\beta$  staining on total thymocytes (left). Discrete developmental stages were defined by surface HSA and TCR $\beta$  expression. IL-7R $\alpha$  and  $\gamma c$  expression (open histograms) were assessed on gated thymocytes and overlaid with control antibody staining (shaded histogram) (middle). Contour plots show CD4/CD8 profiles of gated thymocyte populations (right). Data are representative of 6 independent experiments. (b)  $\gamma c$  protein and mRNA expression in pre-selection DP and post-selection SP thymocytes.  $\gamma c$  surface protein levels on gated DP (CD4<sup>+</sup>CD8<sup>+</sup>) and SP (TCR $\beta$ <sup>+</sup>HSA<sup>lo</sup>) thymocytes (left). Relative expression of  $s\gamma c$  mRNA in sorted DP and SP thymocytes determined by qRT-PCR (right). Data are the mean and SEM of 4 independent experiments.

**$s\gamma c$  overexpression impairs *i*NKT cell generation.** *i*NKT cells are thymus-generated innate T lineage cells that depend on IL-15 for their development and differentiation<sup>7,31,32</sup>. *i*NKT cells can be identified by their TCR reactivity to lipid-loaded CD1d tetramers (CD1dTet)<sup>33</sup>, and here we found that both frequency and number of CD1dTet<sup>+</sup> *i*NKT cells were significantly reduced in  $s\gamma c$ Tg thymocytes (Fig. 6a). Conventionally, *i*NKT cell development had been understood based on cell surface HSA (CD24), CD44 and NK1.1 expression<sup>34–36</sup>. The most immature CD1dTet<sup>+</sup> *i*NKT cells express high levels of HSA and are defined as stage 0 *i*NKT cells. Upon further maturation, *i*NKT cells lose HSA expression but start expressing CD44 and then NK1.1, so that CD44<sup>-</sup>NK1.1<sup>-</sup> cells are stage 1, CD44<sup>+</sup>NK1.1<sup>-</sup> cells are stage 2, and CD44<sup>+</sup>NK1.1<sup>+</sup> cells are referred to as stage 3 *i*NKT cells<sup>35</sup>. Assessing WT and  $s\gamma c$ Tg thymic *i*NKT cells revealed no significant differences between WT and  $s\gamma c$ Tg mice when comparing in individual stages (Fig. 6b–d). However, there was a significant loss of  $s\gamma c$ Tg *i*NKT cells when comparing the combined frequency of mature *i*NKT cells, *i.e.* stage 1–3 (Fig. 6c). Because the frequency of immature stage 0 *i*NKT cells did not differ between  $s\gamma c$ Tg and WT control mice, these results suggest that  $s\gamma c$  overexpression did not target a specific developmental stage but rather induces an overall reduction of thymic *i*NKT cells.

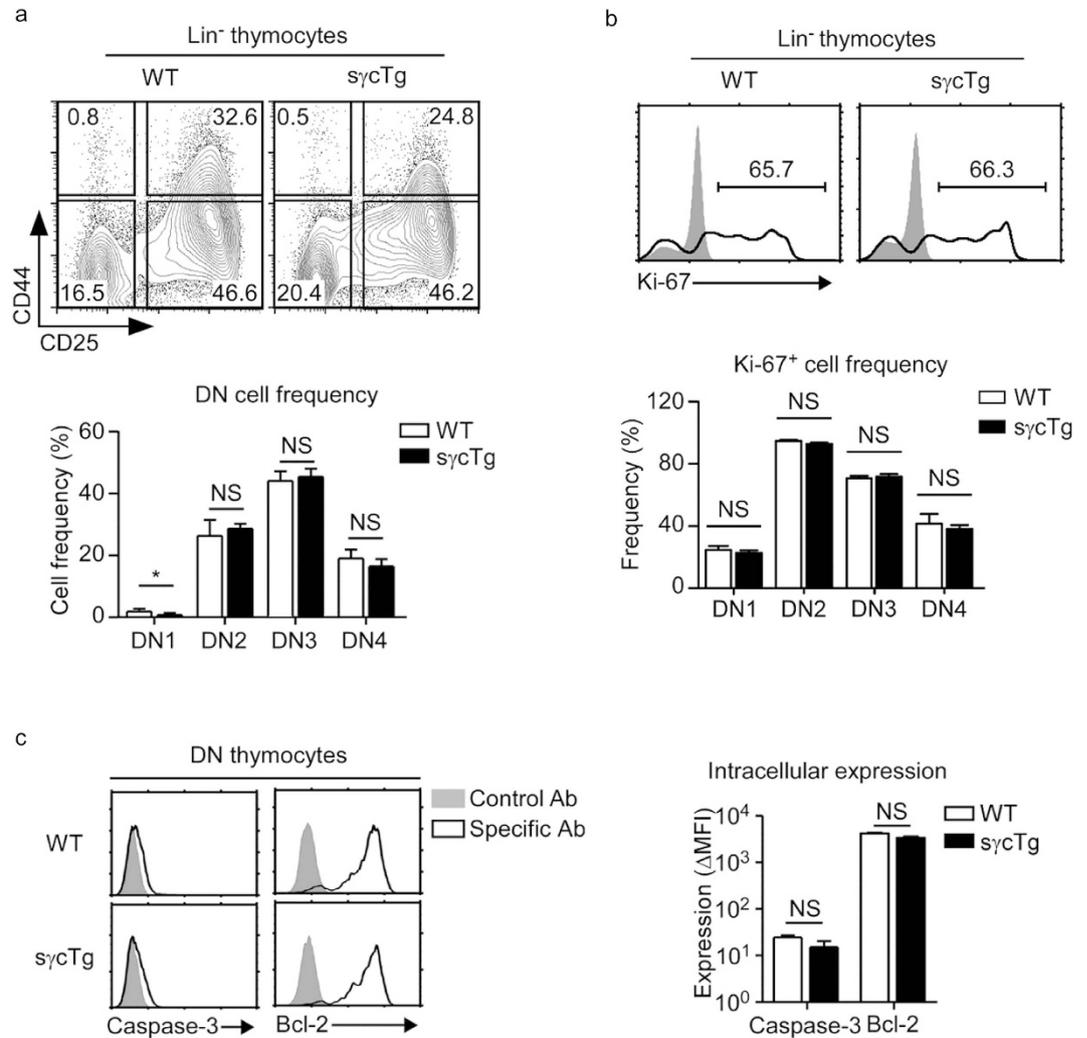

*i*NKT cells can be also categorized into discrete subsets based on their function and transcription factor expression<sup>37</sup>. PLZF<sup>lo</sup> T-bet<sup>+</sup> cells correspond to IFN $\gamma$ -producing NKT1, PLZF<sup>hi</sup>ROR $\gamma$ t<sup>-</sup> cells are IL-4-producing

**Figure 3. Thymocyte development and differentiation in  $s\gamma c$ -transgenic mice.** (a) Total thymocyte numbers in  $s\gamma cTg$  and WT control mice. M,  $s\gamma c$  medium expresser; H,  $s\gamma c$  high expresser. Results are the mean and SEM of 12 independent experiments. (b) CD4 versus CD8 profile of total thymocytes (top) and TCR $\beta^{hi}$  gated thymocytes (bottom) in WT and  $s\gamma cTg$  mice. (c) CD4/CD8 ratio of mature SP thymocytes (left) and frequency of DN thymocytes (right) in WT and  $s\gamma cTg$  mice. (d) Cell numbers of thymocyte subsets in WT and  $s\gamma cTg$  mice. Data are summary of 8 independent experiments with each 10 WT and 15  $s\gamma cTg$  mice.

NKT2, and PLZF<sup>int</sup>ROR $\gamma t^+$  are IL-17-producing NKT17 cells<sup>38</sup>. In C57BL/6 (B6) WT mice, the majority of thymic *i*NKT cells are NKT1 cells with only few NKT2 and NKT17 cells. Such *i*NKT cell distribution is not developmentally fixed, and changes with mouse strains as illustrated by significantly increased NKT2 and NKT17 cell percentages in BALB/c mice (Fig. 6e)<sup>37</sup>. We found that  $s\gamma cTg$  mice, which were maintained on a B6 background, showed identical distribution of NKT subsets to control WT B6 cells (Fig. 6e). Additionally, when dividing *i*NKT cells into two major subsets of CD4<sup>+</sup> and DN *i*NKT cells<sup>32</sup>, we also did not find any difference between  $s\gamma cTg$  and WT mice (Fig. 6f). Collectively, these results demonstrate that  $s\gamma c$  overexpression is detrimental for thymic *i*NKT cell generation, and that  $s\gamma c$  affected *i*NKT cell frequency and number without targeting a specific *i*NKT subset or specific developmental stage.

**$s\gamma c$  interferes with IL-15 signaling in *i*NKT cells.** To further understand the molecular basis of *i*NKT cell loss in  $s\gamma cTg$  mice, next we examined whether increased  $s\gamma c$  expression is a cell intrinsic requirement to suppress *i*NKT cell generation. We generated bone marrow (BM) chimeras where WT origin donor cells were used to reconstitute thymus development in RAG-deficient host mice, either alone or mixed at an unequal ratio (1:2) with  $s\gamma cTg$  origin bone marrow cells. When analyzing the frequency of WT origin (CD45.1) *i*NKT cells, we found that WT origin BM cells gave rise to significantly reduced frequencies of *i*NKT cells, if they developed in a mixed thymic environment with  $s\gamma cTg$  origin thymocytes. Thus,  $s\gamma cTg$  origin BM cells impaired the generation of *i*NKT cells not only for  $s\gamma cTg$  but also for WT *i*NKT cells (Fig. 7a). These results indicate that  $s\gamma c$ 's effect to suppress *i*NKT cell development is mediated by a cell extrinsic mechanism.

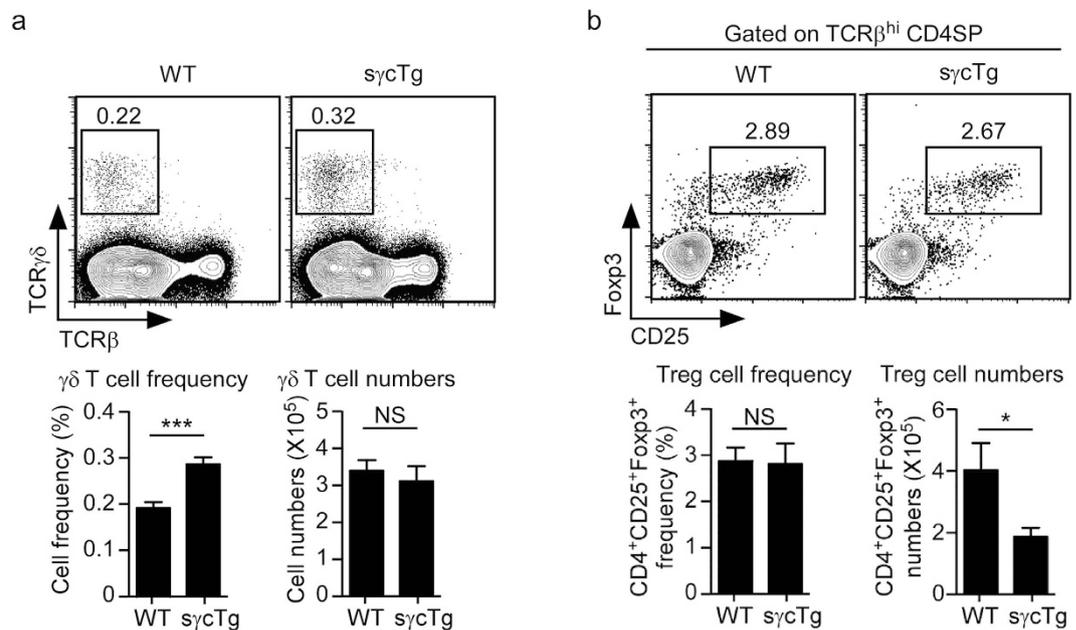

**Figure 4.** DN stages differentiation in WT and sγcTg mice. (a) DN1–DN4 differentiation in lineage marker negative (Lin<sup>-</sup>) DN thymocytes of WT and sγcTg mice (top). Bar graph shows frequencies of individual DN subsets (bottom). Data are the summary of 3 independent experiments with a total of 5 WT and 8 sγcTg mice. (b) Intracellular Ki-67 staining of Lin<sup>-</sup> DN thymocytes in WT and sγcTg mice (top). Bar graph shows Ki-67<sup>+</sup> frequencies in individual DN subsets (bottom). Data are the summary from each two WT and sγcTg mice. (c) Caspase-3 activity and intracellular Bcl-2 expression were determined by flow cytometry in DN thymocytes of WT and sγcTg mice (left). Bar graphs show mean and SEM of each 3 WT and sγcTg mice (right).

iNKT cell development in the thymus depends on IL-15<sup>7,20,21,39</sup>, and defect in iNKT cell generation in sγcTg mice could be a direct consequence of impaired IL-15 signaling. Thus, we assessed expression of surface γc and IL-2Rβ which are the signaling units of a functional IL-15 receptor<sup>40</sup>. We did not find any significant difference in γc and IL-2Rβ expression between WT and sγcTg iNKT cells, which indicated that sγcTg did not impair iNKT cell generation because of defects in cytokine receptor expression (Fig. 7b). To further examine if sγc protein interferes with IL-15 signaling, we examined IL-15 downstream signaling in iNKT cells in the presence or absence of recombinant sγc proteins. Recombinant sγc proteins were produced in 293 T cells, and we confirmed successful formation of disulfide-linked sγc homo-dimers which represent the bioactive form of sγc protein (Fig. 7c)<sup>24</sup>.

IL-15 signaling is considered critical for iNKT cells because it induces expression of anti-apoptotic proteins<sup>6</sup>. Bcl-2 is a pro-survival factor downstream of IL-15 signaling, and we found that IL-15-induced Bcl-2 expression was profoundly impaired in the presence sγc proteins. In particular, recombinant sγc interfered with the pro-survival effect of IL-15 during *in vitro* culture of thymic iNKT cells, as illustrated by significantly increased Annexin V binding (Fig. 7d) and diminished Bcl-2 expression (Fig. 7e). Thus, sγc inhibits iNKT cell development in the thymus, presumably by inhibiting IL-15 signaling.

## Discussion

Generation of soluble γc cytokine receptors through alternative pre-mRNA splicing results in two distinct but interlaced events: production of sγc proteins and diminished surface γc protein expression<sup>24</sup>. Both events are detrimental for γc cytokine signaling. Notably, the effect of alternative splicing is limited to sγc producing cells

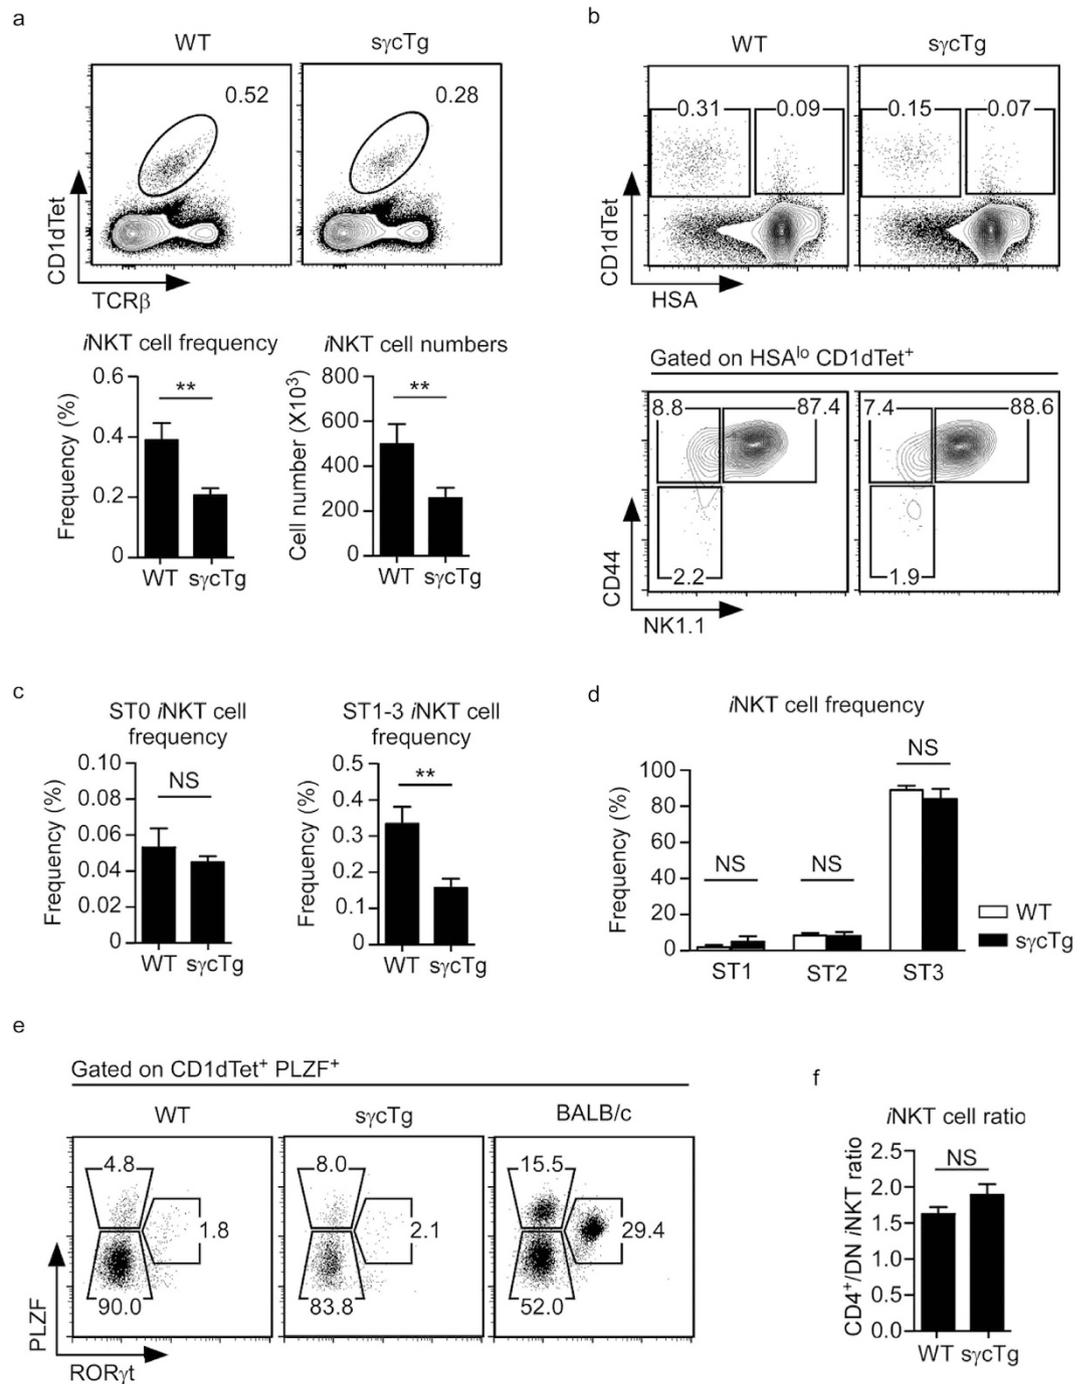

**Figure 5. Thymic  $\gamma\delta$  T cell and Foxp3<sup>+</sup> Treg cell generation are unaffected in s $\gamma$ cTg mice.** (a) Frequency and number of  $\gamma\delta$  T cells were determined from WT and s $\gamma$ cTg thymocytes. Data are the mean and SEM of 11 s $\gamma$ cTg and WT control thymocytes. (b) Frequency and number of Foxp3<sup>+</sup> Treg cells were determined from WT and s $\gamma$ cTg mice. Data are the mean and SEM of 11 s $\gamma$ cTg and WT control thymocytes.

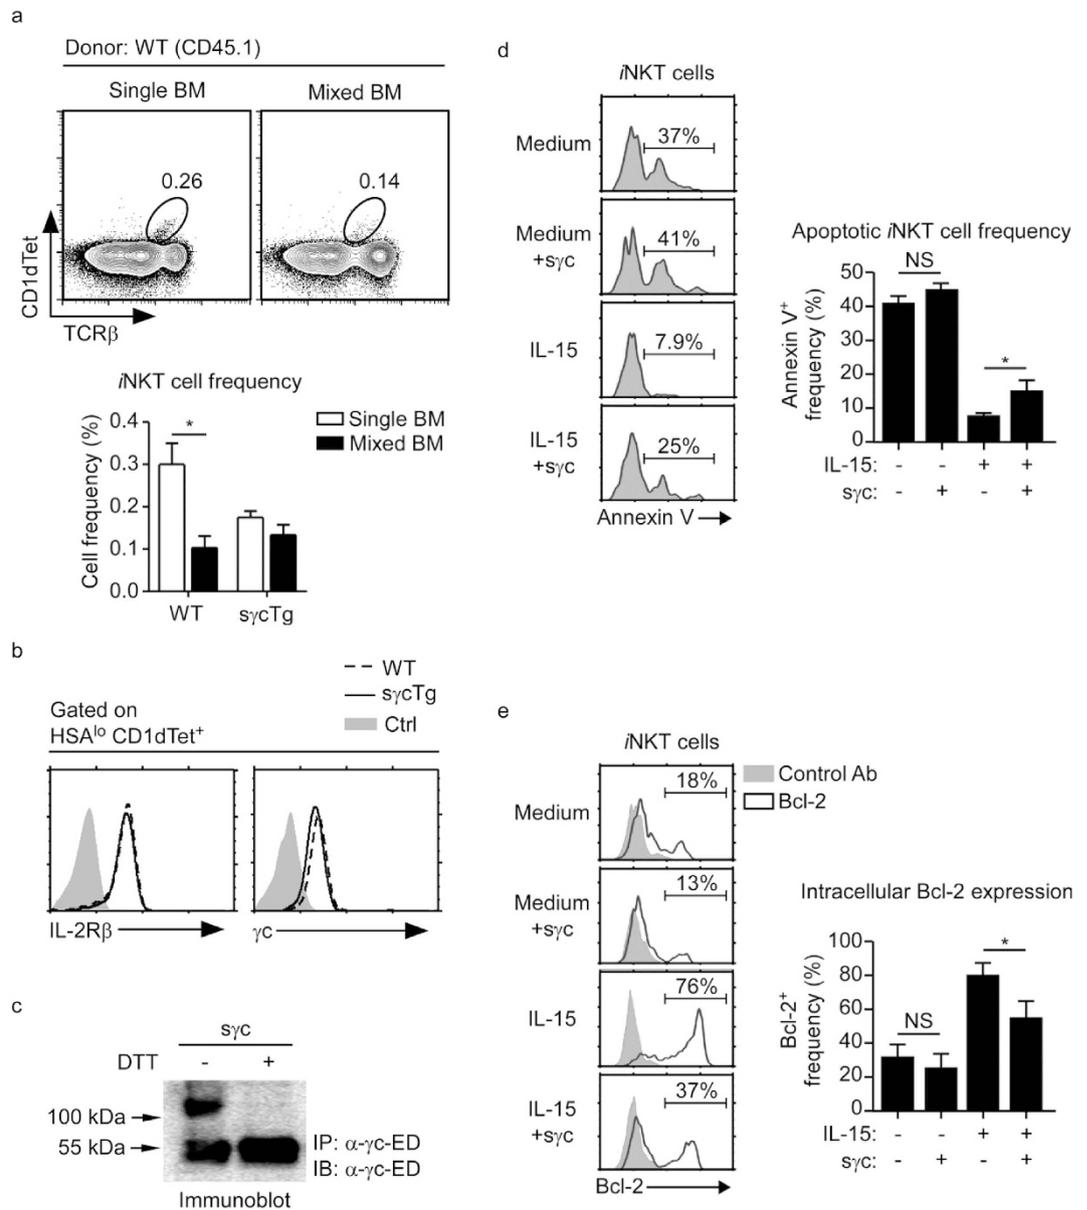

themselves, but secretion of s $\gamma$ c proteins can influence the function of other cells *in trans*. Thus, the physiological role of s $\gamma$ c proteins can be wide-ranging and diverse. Here we assessed the effect of s $\gamma$ c expression on thymic development, and we show that increased s $\gamma$ c production results in impaired thymopoiesis, which is a process dependent on IL-7 signaling<sup>3</sup>, and also in diminished *i*NKT cell generation, which is an event dependent on IL-15 signaling<sup>7,21,39</sup>. Generation of IL-2-dependent Foxp3<sup>+</sup> Treg cells or IL-7-dependent CD8SP thymocytes<sup>5,10,41</sup>, on the other hand, were not affected. These results propose a hierarchy in  $\gamma$ c cytokine responsiveness of post-selection thymocytes, with IL-15 being highly susceptible to increased concentrations of inhibitory s $\gamma$ c proteins, and IL-2 and IL-7 signaling more resistant to s $\gamma$ c-mediated inhibition. Collectively, this study reports a new role for s $\gamma$ c in suppressing IL-15 signaling, and it demonstrates that s $\gamma$ c can affect generation and differentiation of mature T cell subsets in the thymus.

Because s $\gamma$ c is highly expressed by DP thymocytes and because DP thymocytes comprise the vast majority (~85%) of thymocytes<sup>42</sup>, these results further suggest a role for DP thymocytes as a major source of s $\gamma$ c protein that dampens  $\gamma$ c cytokine signaling in the thymus. Consequently, secretion of s $\gamma$ c proteins represents a new function for DP cells, and it suggests that DP thymocytes play an active role in thymic T cell differentiation by modulating  $\gamma$ c cytokine signaling. Conventionally, DP thymocytes have been considered as only a transient developmental stage that is short-lived and that serves no other purpose than providing a pool of random TCR repertoire to be positively selected by the thymic self-peptide/MHC complexes<sup>43,44</sup>. In fact, DP thymocytes do not produce cytokines, and they are not considered to participate in T cell selection or maturation. Moreover, DP thymocytes are metabolically inactive and do not consume nutrients or compete for pro-survival factors<sup>41</sup>. Along these lines, termination of IL-7R $\alpha$  expression on DP thymocytes has been suggested to prevent DP cells from consuming IL-7 which would interfere with IL-7-dependent proliferation of DN thymocytes<sup>18,23</sup>. Thus, DP thymocytes are thought to be a developmentally inert population that do not affect or control differentiation or selection of T cells in the thymus. On the other hand, there is an increasing body of evidence that shows DP thymocytes actively participating in T cell development in a cell extrinsic fashion. Such an idea is illustrated by the requirement for DP thymocytes to promote  $\gamma\delta$  T cell signature gene expression in immature DN thymocytes<sup>45</sup>, and also by a requirement for SLAM-SLAM homotypic interactions among DP thymocytes for positive selection of *i*NKT cells<sup>46,47</sup>. In the current study, we report a new mechanism of how DP cells affect thymic T cell differentiation, which is through the secretion of inhibitory s $\gamma$ c proteins. We think that s $\gamma$ c is the first of a class of soluble factors that are expressed by DP cells to interfere with thymic development. S $\gamma$ c differs from other factors expressed by DP thymocytes, such as lymphotoxin and SLAM<sup>46,47</sup>, because it is not expressed in a membrane-bound form and does not require cell-cell contact. Collectively, DP thymocytes are a major source of s $\gamma$ c proteins, and s $\gamma$ c sets the threshold for  $\gamma$ c cytokine signaling and tunes  $\gamma$ c cytokine responsiveness during T cell development in the thymus.

The inhibitory mechanism of s $\gamma$ c proteins has been previously described<sup>24</sup>. In brief, s $\gamma$ c proteins form homo-dimers that bind with high affinity to unliganded cytokine receptors, such as IL-7R $\alpha$  and IL-2R $\beta$ . Direct binding of s $\gamma$ c to IL-7R $\alpha$  or IL-2R $\beta$  sequesters these receptors and can prevent them from binding to membrane  $\gamma$ c proteins, which is necessary for cytokine signaling. Because IL-2 and IL-15 share the same IL-2R $\beta$ / $\gamma$ c complex for ligand binding and signaling<sup>1</sup>, by implication, s $\gamma$ c binding to IL-2R $\beta$  should interfere with both IL-2 and IL-15 signaling. Interestingly, during s $\gamma$ cTg T cell development, we found that IL-15 but not IL-2-dependent events were impaired.

**Figure 6. Impaired generation of thymic iNKT cells in  $s\gamma cTg$  mice.** (a) Frequency and number of iNKT cells in WT and  $s\gamma cTg$  thymocytes. Data show summary (mean  $\pm$  SEM) from 13  $s\gamma cTg$  and 9 WT control thymocytes. (b) iNKT cell stages in WT and  $s\gamma cTg$  thymic iNKT cells. CD1dTet<sup>+</sup> HSA<sup>lo</sup> mature iNKT cells (top) were assessed for CD44 and NK1.1 expression (bottom). (f) CD4<sup>+</sup> versus DN iNKT cell ratio in WT and  $s\gamma cTg$  thymocytes. Data show mean and SEM of 3 independent experiments with each 3 WT and 4  $s\gamma cTg$  mice.

**Figure 7. Recombinant  $s\gamma c$  proteins suppress IL-15 signaling.** (a) *i*NKT cells in thymus of bone marrow chimeric mice. Bone marrow of WT (CD45.1) and  $s\gamma cTg$  (CD45.2) mice were transferred into irradiated RAG-deficient mice, and thymocytes were analyzed 8 weeks after reconstitution. *i*NKT cell generation was assessed in WT-origin donor cells in single WT (single BM) or unequally-mixed (1:2 ratio of WT versus  $s\gamma cTg$ , mixed BM) bone marrow chimeric mice. Bar graphs show percentages of *i*NKT cells among CD45.1<sup>+</sup> or CD45.2<sup>+</sup> thymocytes in single BM and mixed BM mice. Data are representative and summary of 3 independent experiments. (b) Surface IL-2R $\beta$  and  $\gamma c$  expression on mature HSA<sup>lo</sup>CD1dTet<sup>+</sup>-gated WT and  $s\gamma cTg$  *i*NKT cells. Results are representative of 6  $s\gamma cTg$  and 4 WT control mice from 2 independent experiments. (c) Expression of recombinant  $s\gamma c$  proteins. Culture supernatant of  $s\gamma c$  expressing 293 T cells were immunoprecipitated (IP) and immunoblotted (IB) for  $s\gamma c$  proteins using anti- $\gamma c$  ectodomain antibodies ( $\alpha$ - $\gamma c$ -ED). Immunoprecipitates were resolved by SDS-PAGE under reducing (+ DTT) or non-reducing conditions. (d) Thymic *i*NKT cell survival upon 3-day *in vitro* IL-15 stimulation in the presence or absence of recombinant  $s\gamma c$  proteins. Cell viability was determined by Annexin V staining. Histograms are representative of 3 independent experiments (left). Bar graphs show mean and SEM of 3 independent experiments (right). (e) Intracellular Bcl-2 expression in thymic *i*NKT cells stimulated for 3 days with IL-15 in the presence or absence of recombinant  $s\gamma c$  proteins. Histograms show representative results from three independent experiments (left). Bar graphs show mean and SEM of 3 independent experiments (right).

*i*NKT cell development was significantly blunted but Foxp3<sup>+</sup> Treg cell generation remained intact. These results suggested distinct susceptibility of IL-2 versus IL-15 signaling to  $s\gamma c$ -mediated inhibition. Why IL-15 signaling would be more perceptible to  $s\gamma c$  blockade than IL-2 signaling is not clear. As a potential explanation, we considered the

fact that IL-15 signaling requires IL-15 trans-presentation by IL-15R $\alpha$ <sup>48</sup>, and that *i*NKT cell development depends on IL-15R $\alpha$ -mediated IL-15 trans-presentation by thymic stromal cells<sup>49,50</sup>. Formation of a quaternary complex of IL-2R $\beta$ / $\gamma$ c hetero-dimers on one cell with an IL-15/IL-15R $\alpha$  complex on another cell could be more susceptible to steric hindrance by  $\gamma$ c proteins than the assembly of a functional IL-2R $\alpha$ ,  $\beta$ / $\gamma$ c signaling complex on the same cell. Altogether, the current results demonstrate an interference of  $\gamma$ c with IL-15-dependent steps during T cell development, and confirm the *in vivo* significance of  $\gamma$ c proteins in thymocyte differentiation.

The roles of  $\gamma$ c cytokines in thymocyte development are well appreciated. Positive selection and lineage choice are two distinct events<sup>51</sup>. While TCR signaling controls positive selection,  $\gamma$ c signaling plays a critical role in lineage fate decision and differentiation of post-selection thymocytes<sup>52</sup>. Following positive selection, IL-7 signaling induces Runx3 expression and imposes CD8 lineage choice<sup>10,16,19</sup>, whereas IL-2 signaling is necessary to upregulate Foxp3 and promote Treg cell differentiation in CD4SP cells<sup>5</sup>. For *i*NKT cells, IL-15 is a critical maturation and differentiation signal, and the absence of IL-15 results in paucity of *i*NKT cells in both the thymus and peripheral tissues<sup>7,20,39</sup>. Thus, the reduced thymic *i*NKT cell numbers in  $\gamma$ cTg is in line with impaired IL-15 signaling by  $\gamma$ c and the requirement for IL-15 in *i*NKT cell generation.

Importantly, thymic *i*NKT cells comprise a functionally and phenotypically heterogeneous population that contains distinct subsets of *i*NKT cells with differing degree of IL-15 dependency<sup>6,37</sup>. NKT1 cells, which correspond largely to stage 3 *i*NKT cells, express high levels of T-bet which in turn is critical for their maturation, survival and effector function<sup>53,54</sup>. Both NKT1 lineage choice and T-bet upregulation depend on IL-15 signaling<sup>6,55</sup>, so that impaired IL-15 signaling mostly affects NKT1 cells. NKT17 cells, on the other hand, depend exclusively on IL-7, but not IL-15, for their survival and homeostasis<sup>56</sup>. Thus, it was curious that  $\gamma$ c overexpression not only reduced number and frequency of IL-15-dependent NKT1 cells, but also of NKT17 and even NKT2 cells. However, these results can be reconciled when taking into account that  $\gamma$ c does only not inhibit IL-15 signaling, but also signaling by IL-2, IL-7, and presumably other  $\gamma$ c cytokines<sup>24</sup>. Accordingly,  $\gamma$ c would not only block generation of IL-15-dependent NKT1 cells, but could also impair IL-7-dependent NKT17 cell development in the thymus. Because NKT2 cells were also reduced by  $\gamma$ c overexpression, this scenario further suggests a role of  $\gamma$ c signaling in NKT2 lineage differentiation too.

Finally, the current results do not exclude the possibility that  $\gamma$ cTg could have interfered with cell proliferation to diminish thymic *i*NKT cell numbers. Positively selected stage 0 *i*NKT cells undergo massive (~100 fold) expansion upon differentiation into stage 1 *i*NKT cells which is dependent on c-Myc<sup>57</sup>. What cellular signals drive the proliferation is not clear, and we cannot formally discard the possibility that IL-15 could be involved in c-Myc-dependent proliferation during stage 0/1 transition. Whether this is indeed the case still remains to be tested. In sum, the inhibitory effect of  $\gamma$ c on IL-15 signaling *in vivo* and the impaired generation of thymic *i*NKT cells in  $\gamma$ cTg mice put forward a model of cytokine regulatory mechanism that requires integration of a role of  $\gamma$ c in controlling  $\gamma$ c cytokine signaling.

## Materials and Methods

**Mice.** C57BL/6 (CD45.2), CD45.1 congenic mice, and RAG<sup>-/-</sup> mice were obtained from Charles River, Wilmington, MA, and from the Orient Bio, Korea. Soluble  $\gamma$ c-transgenic mice were described and maintained in our colony<sup>24</sup>. Animal experiments were approved by the Pusan National University Institutional Animal Care and Use Committee (PNU-2014-0620) and the NCI Animal Care and Use Committee. All mice were cared for in accordance with Pusan National University School of Medicine and NIH guidelines.

**Flow cytometry.** Single cell suspensions were prepared from the thymus of indicated mice. Data were acquired using LSR Fortessa or LSRII flow cytometers (BD Biosciences) and analyzed using FlowJo. Live cells were gated by forward scatter exclusion of dead cells stained with propidium iodide. The following antibodies were used for staining: TCR $\beta$  (H57-597), HSA (30-F1), IL-7R $\alpha$  (A7R34), NK1.1 (PK136), IL-2R $\alpha$  (PC61.5), IL-2R $\beta$  (TM- $\beta$ 31), IL-4R $\alpha$  (M1), Foxp3 (FJK-16s), ROR $\gamma$ t (AKFJS-9) and isotype control antibodies, all from eBioscience; TCR $\gamma$  $\delta$  (GL3), CD44 (IM7),  $\gamma$ c (4G3), CD4 (GK1.5 and RM4.5), and CD8 $\alpha$  (53-6-7) from BD Biosciences; IL-9R $\alpha$  (RM9A4), Bcl-2 (BCL/10C4), PLZF (9E12), and IL-21R (4A9) from BioLegend. Fluorochrome-conjugated CD1d tetramers loaded with PBS-567 and unloaded controls were obtained from the NIH tetramer facility (Emory University, Atlanta, GA). Intracellular Foxp3, PLZF, and ROR $\gamma$ t proteins were detected using a Foxp3 staining kit according to the manufacturer's instructions (eBioscience). Active caspase-3 induction was determined using the CaspGLOW<sup>TM</sup> fluorescein active caspase-3 staining kit (eBioscience).

**Quantitative Real-Time PCR.** Total RNA was isolated from sorted thymocytes with the RNeasy Mini kit (Qiagen). RNA was reverse transcribed into cDNA by oligo (dT) priming with the QuantiTect Reverse transcription kit (Qiagen). Quantitative RT-PCR (qRT-PCR) was performed with an ABI PRISM 7900HT Sequence Detection System and the QuantiTect SYBR Green detection system (Qiagen). Primers sequences are as follows.  $\gamma$ c (F: 5'-CATGAACCTAGATTCTCCCTGCC-3'; R: 5'-TGATGGGGGAATTGGAGIIIICCTCTACA-3') and *Rpl13* (F: 5'-CGAGGCATGCTGCCCCACAA-3'; R: 5'-AGCAGGGACCACCATCCGCT-3'). Gene expression values were normalized to those of *Rpl13* in the same sample.

**Expression of recombinant soluble  $\gamma$ c protein.** Recombinant  $\gamma$ c proteins were produced by transient transfection of 293 T human embryonic kidney cells with a mammalian expression vector pEGFP-N1 (Clontech) encoding a murine  $\gamma$ c cDNA. Cells were transfected with Lipofectamine<sup>TM</sup> 2000 (Invitrogen). Culture supernatant containing  $\gamma$ c proteins was collected 3 days after transfection and analyzed by Western blot for recovery and purity. Concentration of  $\gamma$ c protein was measured by ELISA as previously described<sup>24</sup>.

**In vitro stimulation with recombinant IL-15.** Thymocytes were incubated *in vitro* with 20 ng/ml recombinant human IL-15 (Peprtech) in the presence or absence of recombinant  $\gamma$ c (500 ng/ml). Thymocytes were harvested 3 days after incubation, and stained for intracellular Bcl-2 expression. Annexin V staining was performed according to the manufacturer's instructions (BD Biosciences).

**DN thymocyte subsets analysis.** For DN1-DN4 thymocyte analysis, whole thymocytes were first incubated with the following biotinylated antibodies; anti-TCR $\beta$ , -B220, -CD8 $\beta$ , -GL3, -DX5, -MAC1, and -GR1, followed by FITC-conjugated streptavidin. FITC-signal negative thymocytes were considered as lineage marker negative cells (Lin<sup>-</sup>) and assessed for CD44 and CD25 expression using APC-conjugated anti-CD44 and PE-conjugated anti-CD25 antibodies (all from BD Biosciences). Intracellular Ki-67 staining of DN subsets was performed after fixation and permeabilization (Foxp3 transcription factor staining buffer set, eBioscience) of surface-stained thymocytes using anti-Ki-67 antibodies (eBioscience).

**Bone marrow chimeras.** Radiation bone marrow chimeras were constructed by reconstituting lethally irradiated (600 Rad) RAG<sup>-/-</sup> host mice with a total of  $15 \times 10^6$  T cell-depleted bone marrow (BM) cells either from WT (CD45.1) or  $\gamma$ cTg (CD45.2). For unequal bone marrow reconstitution, T cell-depleted BM cells from WT and  $\gamma$ cTg mice were mixed at 1:2 ratio (WT: $\gamma$ cTg), and  $15 \times 10^6$  mixed BM cells were injected into irradiated RAG<sup>-/-</sup> host mice. Chimeric mice were analyzed 8 weeks after reconstitution. Thymocytes from both BM chimeric mice were gated on CD45.1 or CD45.2 to distinguish WT and  $\gamma$ cTg donor cells.

**Statistical analysis.** Data are shown as mean  $\pm$  SEM. Statistical differences were analyzed by unpaired two-tailed Student's *t*-test. P values of less than 0.05 were considered significant. \**p* < 0.05, \*\**p* < 0.01, \*\*\**p* < 0.001. All statistical analysis was performed using GraphPad Prism.
