Very recent studies indicate that sulfur atoms with oxidation state 0 or  $-1$ , called sulfane sulfurs, are the actual mediators of some physiological processes previously considered to be regulated by hydrogen sulfide (H<sub>2</sub>S). 3-Mercaptopyruvate sulfurtransferase (3MST), one of three H<sub>2</sub>S-producing enzymes, was also recently shown to produce sulfane sulfur (H<sub>2</sub>S<sub>n</sub>). Here, we report the discovery of several potent 3MST inhibitors by means of high-throughput screening (HTS) of a large chemical library (174,118 compounds) with our H<sub>2</sub>S-selective fluorescent probe, HSip-1. Most of the identified inhibitors had similar aromatic ring-carbonyl-5-pyrimidone structures. Among them, compound 3 showed very high selectivity for 3MST over other H<sub>2</sub>S/sulfane sulfur-producing enzymes and rhodanese. The X-ray crystal structures of 3MST complexes with two of the inhibitors revealed that their target is a persulfurated cysteine residue located in the active site of 3MST. Precise theoretical calculations indicated the presence of a strong long-range electrostatic interaction between the persulfur anion of the persulfurated cysteine residue and the positively charged carbonyl carbon of the pyrimidone moiety of the inhibitor. Our results also provide the experimental support for the idea that the 3MST-catalyzed reaction with 3-mercaptopyruvate proceeds via a ping-pong mechanism.

Hydrogen sulfide (H<sub>2</sub>S) plays roles in many physiological processes in mammals, including relaxation of vascular smooth muscles<sup>1</sup>, regulation of inflammation<sup>2</sup>, and inhibition of insulin signaling<sup>3</sup>. H<sub>2</sub>S generated by many prokaryotic species is also related to antibiotic resistance, serving to mitigate oxidative stress imposed by antibiotics<sup>4</sup>. Thus, H<sub>2</sub>S is an important reactive sulfur species not only in mammals, but also in bacteria. More recently, it has been proposed that sulfane sulfurs<sup>5</sup>, i.e., sulfur atoms with oxidation state 0 or -1, existing in the form of polysulfides (H<sub>2</sub>S<sub>n</sub>), glutathione persulfide (GSSH), glutathione trisulfide (GSSSG), cysteine persulfide (CysSSH) and so on, actually mediate some of the reported biological activities previously thought to be regulated by H<sub>2</sub>S<sup>6–11</sup>. So, there is increasing interest in these reactive sulfur species<sup>5</sup>.

So far, three H<sub>2</sub>S-producing enzymes have been reported: cystathionine  $\gamma$ -lyase (CSE), cystathionine  $\beta$ -synthase (CBS) and 3-mercaptopyruvate sulfurtransferase (3MST)<sup>12</sup>, and recently these enzymes have also been reported to produce persulfides and polysulfides<sup>7–9</sup>. CSE and CBS produce H<sub>2</sub>S or cysteine persulfides/polysulfides by using L-cysteine or L-cystine as a substrate, respectively, and are involved in relaxation of vascular smooth muscles and cytoprotection<sup>1,7,8</sup>. 3MST produces H<sub>2</sub>S from 3-mercaptopyruvate (3MP), which is generated from L-cysteine and  $\alpha$ -ketoglutarate ( $\alpha$ -KG) by cysteine aminotransferase (CAT) in the presence of the cofactors thioredoxin and dihydrolipoic acid<sup>13</sup>. It also produces polysulfides in the brain<sup>9</sup>.

To study the physiological roles and redox biology of these reactive sulfur species, we require inhibitors able to regulate the activities of the above three enzymes. Several CSE inhibitors, such as propargylglycine (PAG) and  $\beta$ -cyano-L-alanine (BCA), have been reported<sup>14,15</sup>, and PAG has been widely used in studies of the roles of H<sub>2</sub>S in mammalian physiology. Aminoxyacetic acid (AOAA) is frequently used as a CBS inhibitor. On the other hand, in the case of 3MST, only non-selective and weak substrate-like inhibitors have so far been reported<sup>16–19</sup>, and none of them is suitable for biological studies. Therefore, development of a 3MST-selective inhibitor would be extremely useful for biological studies of H<sub>2</sub>S and persulfides/polysulfides, and for detailed examination of the functions of 3MST.

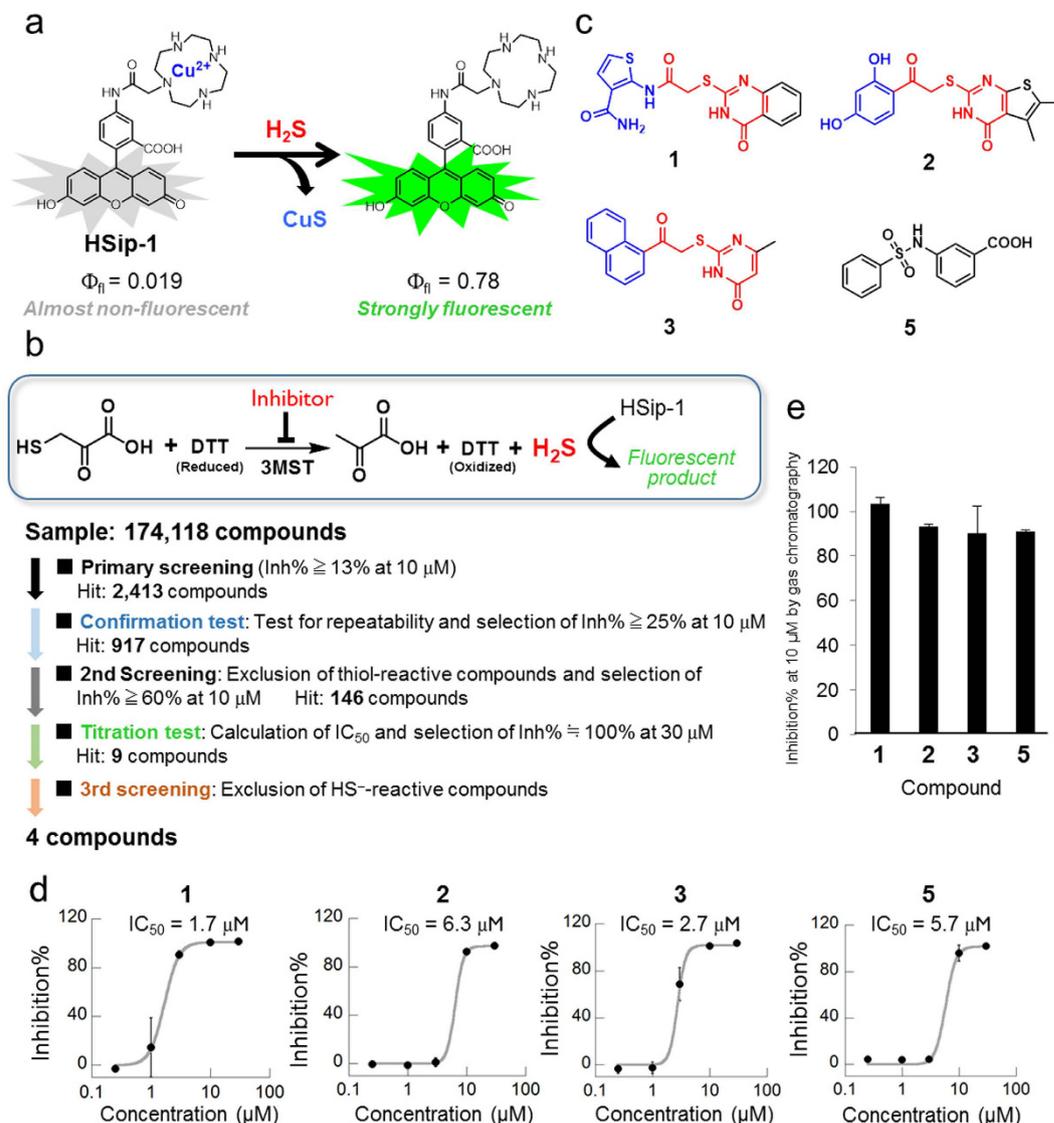

Here, we established a novel high-throughput screening (HTS) system by utilizing our previously developed H<sub>2</sub>S-selective fluorescent probe, HSip-1<sup>20</sup>, and discovered several 3MST-selective inhibitors sharing a similar chemical structure by screening of a large chemical library (174,118 compounds) of the Drug Discovery Initiative, The University of Tokyo, Japan. Based on crystal structure determinations of 3MST complexes with two of the inhibitors, as well as theoretical calculations, we suggest that a unique long-range electrostatic interaction between the inhibitor and the persulfurated cysteine residue located in the enzyme active site plays a key role in inhibitor binding. We also discuss the implications of our findings for the reaction mechanism of the enzyme.

## Results

**Construction of HTS system for 3MST inhibitors.** We have previously reported a fluorescent probe for H<sub>2</sub>S, HSip-1, based on azamacrocyclic Cu<sup>2+</sup> complex chemistry (Fig. 1a). HSip-1 can detect H<sub>2</sub>S in aqueous solution with high selectivity over biothiols, inorganic sulfur compounds, reactive oxygen species (ROS) and reactive nitrogen species (RNS), and has excellent photophysical properties for *in vitro* and *in cellulo* assays ( $\Phi_{fl} = 0.019$  and 0.78 in the absence and in the presence of H<sub>2</sub>S, respectively). Since fluorescence detection is rapid and convenient<sup>21</sup>, we used HSip-1 to develop an HTS system for discovery of 3MST-selective inhibitors. For this purpose, we first prepared a large amount of recombinant GST-fused 3MST. We used mouse 3MST (m3MST) because we wished to discover inhibitors that would be suitable for studies of the physiological function of 3MST in mice as model animals. We adopted an *E. coli* expression system in order to obtain a sufficient amount of GST-fused m3MST (GST-3MST) for the HTS (about 30 mg of GST-3MST from 900 mL of LB medium; Supplementary Fig. S1).

In this assay system, GST-3MST produces H<sub>2</sub>S by enzymatic reaction with 3MP and dithiothreitol (DTT) as substrates, and we further added HSip-1 to this solution as a fluorescent probe to monitor H<sub>2</sub>S production; thus, when the enzyme activity is inhibited by a test compound, and consequently the H<sub>2</sub>S production decreases, the fluorescence increase of HSip-1 is suppressed. First, we confirmed that HSip-1 could detect H<sub>2</sub>S produced by 3MST. The fluorescence intensity of HSip-1 in GST-3MST-containing reaction solution dramatically increased after addition of its substrates 3MP and DTT (Supplementary Fig. S2). On the other hand, when GST was used instead of GST-3MST as a negative control, the fluorescence increase of HSip-1 was suppressed. Thus, HSip-1 could detect H<sub>2</sub>S produced by 3MST in terms of a fluorescence increase. Moreover, we optimized the assay conditions in the 384-well HTS format (Supplementary Fig. S3), including appropriate concentrations of 3MST, 3MP and DTT. We also examined the effect of DMSO on this optimized enzymatic reaction of 3MST, because the library compounds are initially dissolved in DMSO as stock solutions. DMSO showed almost no effect on the enzyme activity of 3MST up to at least 5% DMSO (Supplementary Fig. S4).

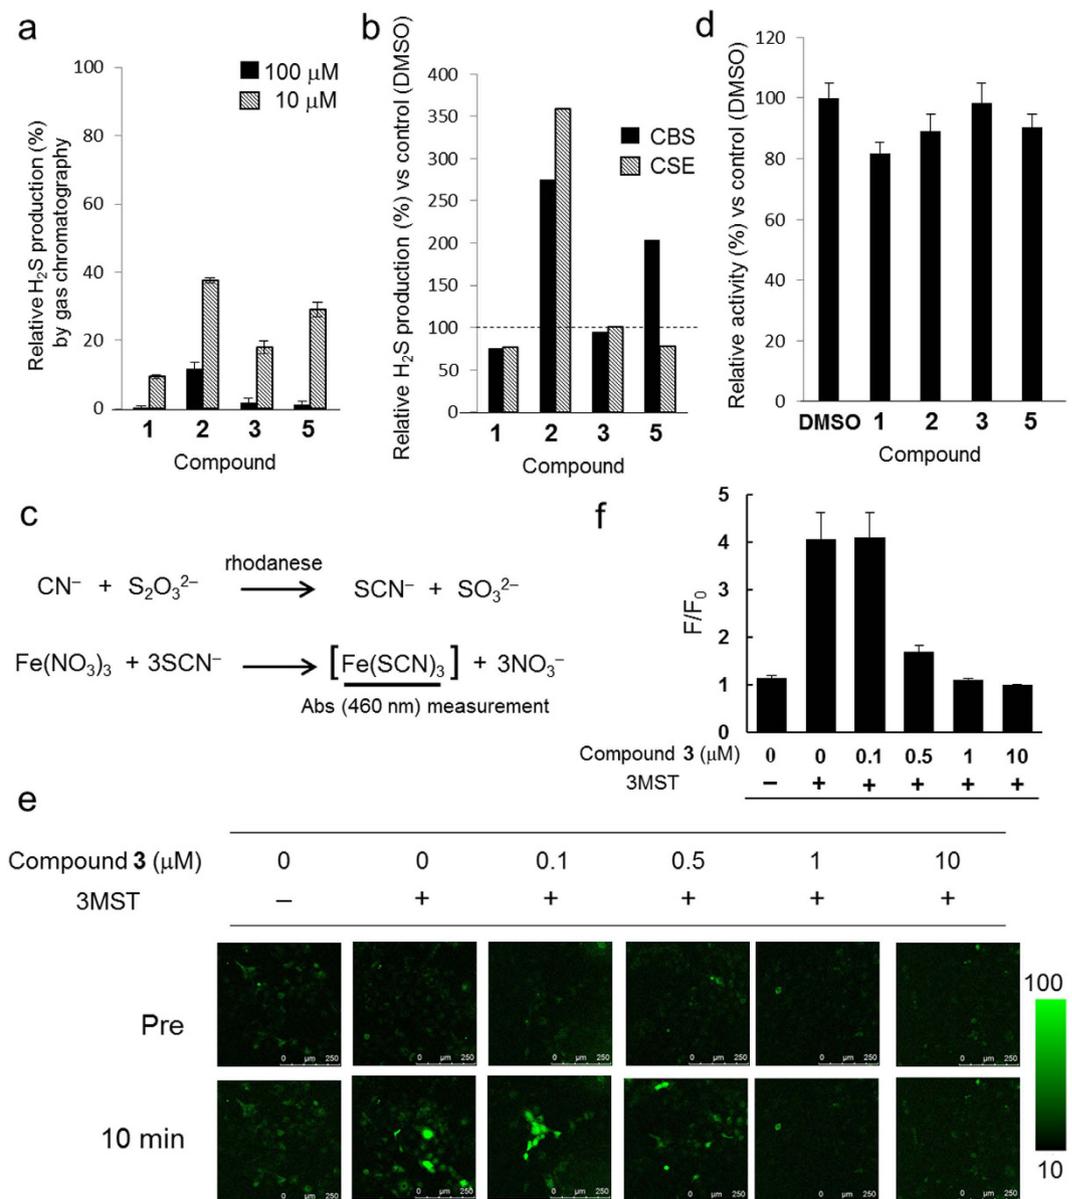

**HTS of a chemical library for 3MST inhibitors.** We performed 3MST inhibitor screening of a chemical library containing 174,118 compounds (Fig. 1b). All compounds were tested at 10  $\mu$ M and compounds showing more than 13% inhibition were selected (primary screening; 2,417 hit compounds) (Supplementary Fig. S3 and S5). We further examined the reproducibility (confirmation test) of the hit compounds identified in the primary screening to eliminate false-positives due, for example, to dispensing errors, leaving 917 hit compounds (Supplementary Fig. S6). The second, non-enzymatic assay was then performed to eliminate false-positive hit compounds, such as naphthoquinone, showing reactivity with substrates 3MP and DTT, leaving 146 hit compounds (Supplementary Fig. S7). In the titration test, we examined the dose-dependency (0.25, 1, 3, 10, 30  $\mu$ M) of 3MST-inhibitory activity of each compound (146 hit compounds in the second screening) to determine the half-maximal (50%) inhibitory concentration (IC<sub>50</sub>). Nine compounds (Fig. 1c, Supplementary Fig. S8) showed dose-dependent inhibition of 3MST, with IC<sub>50</sub> values of 0.23–14.9  $\mu$ M (Supplementary Table S1). In the third screening, we excluded false-positive compounds that directly react with H<sub>2</sub>S (Supplementary Table S2). For this assay, we synthesized a reported small-molecular H<sub>2</sub>S donor<sup>22</sup> that generates H<sub>2</sub>S by reacting with cysteine.

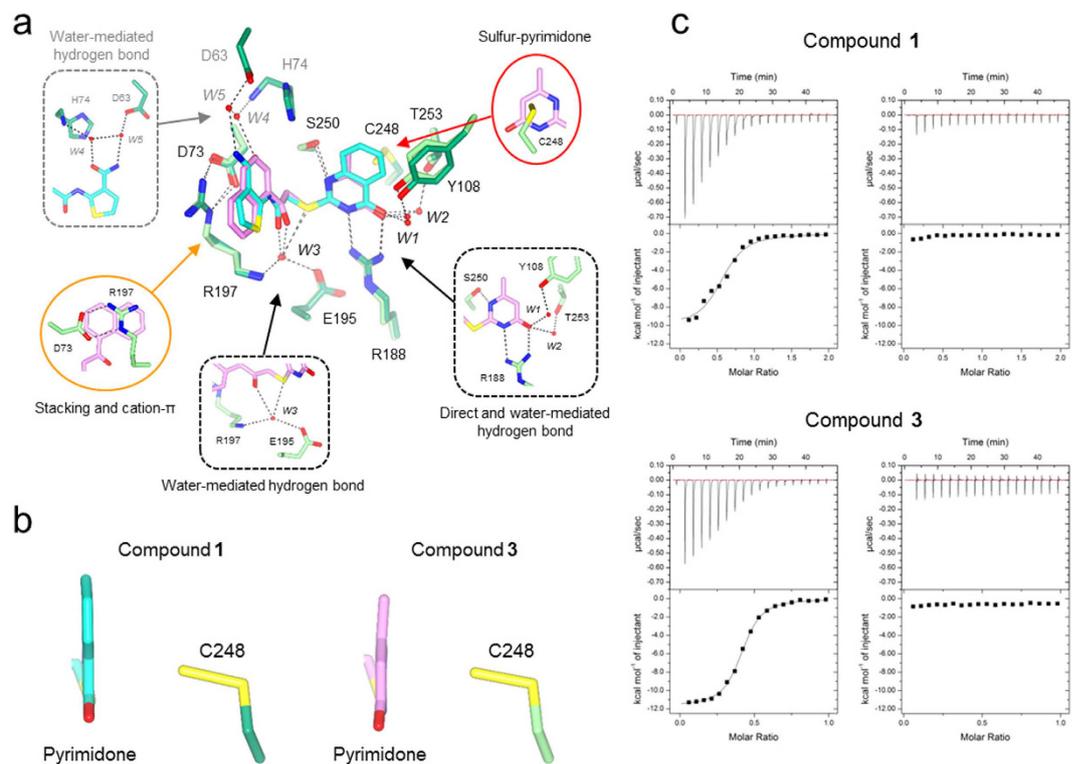

**Figure 1. HTS scheme and hit compounds.** (a) The fluorescent probe for H<sub>2</sub>S, HSip-1, and its fluorescence off/on mechanism in response to H<sub>2</sub>S. (b) Detection system of 3MST enzymatic activity with HSip-1 and the scheme for HTS of a chemical library of 174,118 compounds. (c) The chemical structures of 4 potential inhibitors (hit compounds) for 3MST. (d) Dose-response curves of inhibitory activity of compounds 1, 2, 3 and 5 towards 3MST in the titration test. (e) Inhibitory activity of hit compounds at 10  $\mu M$  measured by gas chromatography.

Based on the results of the titration test and the third screening, we concluded that compound 9 showed weak reactivity with thiol compounds such as 3MP and DTT (Supplementary Table S1), and compounds 6–8 appeared to react with H<sub>2</sub>S (Supplementary Table S2). Based on the structure, compound 9 is considered to be one of the pan-assay interference compounds (PAINS), which show activity across a range of assay platforms and against a range of proteins<sup>23</sup>. Compound 4 was excluded because it has a thiol group and is likely to be readily oxidized to disulfide. On the other hand, compounds 1–3, 5 showed >80% inhibition of 3MST activity at 10  $\mu M$ , and their  $IC_{50}$  values were 2–7  $\mu M$  (Fig. 1c,d). Interestingly, 1–3 all have a similar structural scaffold, i.e., an aromatic ring-carbonyl-S-pyrimidone structure (Fig. 1c). We then confirmed the inhibitory activity of the 4 hit compounds by direct monitoring of H<sub>2</sub>S production by gas chromatography, because we had detected H<sub>2</sub>S production only with the fluorescent probe up to this point. All 4 compounds showed >80% inhibition activity at 10  $\mu M$ , in agreement with the fluorescence results (Fig. 1e, Supplementary Fig. S9).

**Assessment of selectivity of hit compounds for 3MST.** To examine the selectivity of these compounds for 3MST, we measured their inhibitory activity in cell lysate of 3MST-overexpressing HEK293 cells by gas chromatography (Fig. 2a). All 4 compounds showed >85% inhibition at 100  $\mu M$ , and compounds 1 and 3 showed high inhibitory activity (80–90%) even at 10  $\mu M$ . We further examined the selectivity of compounds 1–3 and 5 against the other two H<sub>2</sub>S-producing enzymes, CSE and CBS by gas chromatography. Compound 1 showed about 25%

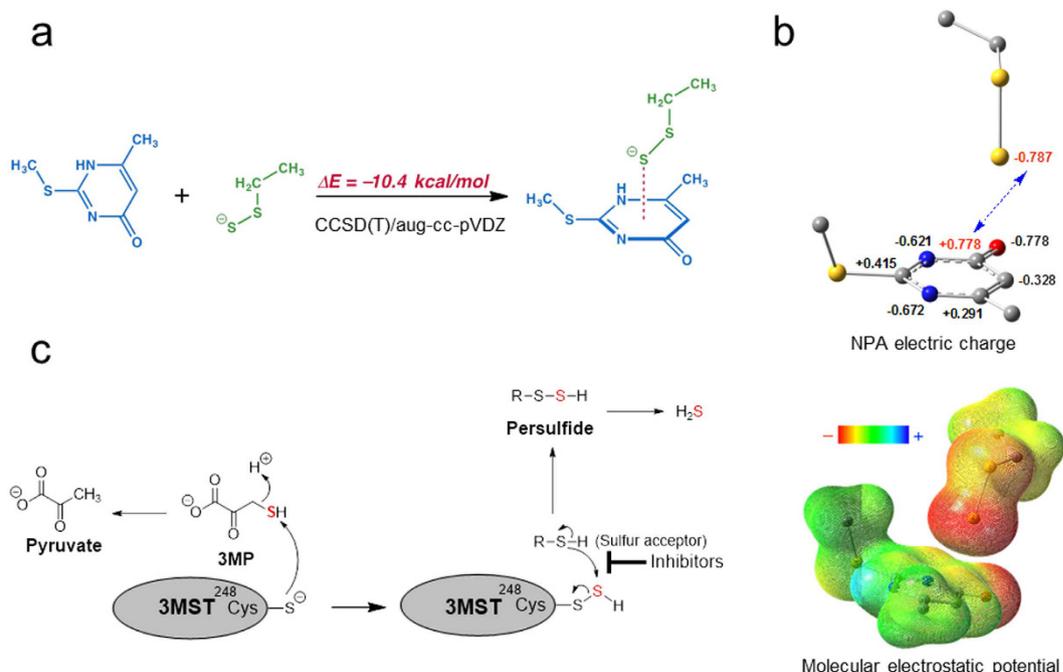

**Figure 2. Selectivity assessment of hit compounds for 3MST over other H<sub>2</sub>S/polysulfides-producing enzymes and rhodanese.** (a) 3MST-Inhibitory activity of hit compounds at 10 and 100 μM in cell lysate of 3MST-expressing HEK293 cells. 100 μM 3MP and 100 μM DTT were added to the solution containing 0.1% DMSO as a cosolvent, and the mixture was incubated at 37 °C for 15 min. H<sub>2</sub>S production was measured by gas chromatography. All data are presented as the mean ± S.D. (100 μM: *n* = 3 or 4; 10 μM: *n* = 3). (b) Selectivity assessment of hit compounds at 100 μM towards CBS and CSE. Only DMSO was added to the control sample instead of DMSO solution containing hit compounds. H<sub>2</sub>S production was monitored by gas chromatography. All data are presented as the mean (*n* = 3). (c) Detection method for rhodanese activity (Sörbo method). (d) Selectivity assessment of hit compounds towards rhodanese. The results are mean ± S.D. (*n* = 4, three times). These values were determined based upon the absorbance of [Fe(SCN)<sub>3</sub>] at 460 nm (Sörbo method). Bovine rhodanese 1.3–1.7 units/mL, substrate: 52 mM Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, 50 mM KCN, 0.004% (w/v) BSA, 100 μM compound and DMSO 1% (v/v) in 88 mM potassium phosphate buffer (pH 8.6) at room temperature for 5 min incubation. (e) Fluorescence confocal microscopic images of live COS7 cells transfected with 3MST or an empty vector<sup>9</sup> as a control. Cells were incubated with 50 μM SSP4, a fluorescent probe for sulfane sulfur, and 10 μM, 1 μM, 0.5 μM, 0.1 or 0 μM compound 3 in DMEM containing 0.6% DMSO for 30 min, then washed with HBSS and placed in fresh DMEM with 0–10 μM compound 3 (Pre). 500 μM 3MP was added to the cells and the cells were incubated for 10 min (10 min). (f) Graphic representation of (e). F/F<sub>0</sub> was calculated by dividing the fluorescence intensity of cells after addition of 500 μM 3MP (10 min) by that of cells before addition of 500 μM 3MP (Pre), then the mean F/F<sub>0</sub> was determined from 5 cells. All data represent the mean ± standard error of the mean (SEM) of three experiments.

**Figure 3. Crystal structure of 3MST-inhibitor complex and ITC analysis.** (a) Detailed view of the active site of the two protein-inhibitor complexes. Residues of 3MST-compound 1 complex (emerald green), residues of 3MST-compound 3 complex (light green), compound 1 (cyan), compound 3 (pink), oxygen atoms of residues and compounds (red), nitrogen atoms (blue), sulfur atoms (yellow), hydrogen bonding (black dotted lines), waters of 3MST-compound 1 complex (red spheres) and waters of 3MST-compound 3 complex (red spheres) are shown. (b) Detailed view of the 4-pyrimidone-like aromatic ring and the side chain of persulfurated C248. The side chain of 3MST-compound 1 complex (emerald green), the side chain of 3MST-compound 3 complex (light green), compound 1 (cyan), compound 3 (pink), oxygen atoms (red), nitrogen atoms (blue) and sulfur atoms (yellow) are shown. (c) ITC analysis of 3MST injected with compound 1 (upper) and compound 3 (bottom). The titration plots (top graph) and fitting curves (bottom graph) of persulfurated 3MST (left) and the non-persulfurated 3MST (right) are shown.

inhibition of recombinant CBS and CSE enzymatic activities, while compound 3 was almost inactive towards CBS and CSE (Fig. 2b). Interestingly, compound 2 enhanced  $\text{H}_2\text{S}$  production by CBS and CSE, but this is possibly due to the direct reaction of 2 with the high concentration of cysteine (10 mM). Compound 5 showed enhancement of  $\text{H}_2\text{S}$  production by CBS only. The mechanisms of enhanced  $\text{H}_2\text{S}$  production by compounds 2 and 5 are under investigation. Finally, we examined the inhibitory activity of the 4 hit compounds towards rhodanese (thiosulfate sulfurtransferase, Type II), which belongs to the same rhodanese/Cdc25 phosphatase superfamily as 3MST<sup>24</sup> and shares high amino acid sequence identity with m3MST (58%; 172/297 amino acids). This enzyme is involved in cyanide metabolism by transferring a sulfur atom to cyanide ion. We monitored the conversion of cyanide ions to thiocyanide ions by rhodanese using the Sörbo method<sup>25</sup> (Fig. 2c, Supplementary Fig. S10), and found that compounds 1, 2, 3 and 5 showed  $18.2 \pm 3.6\%$ ,  $10.9 \pm 5.5\%$ ,  $1.7 \pm 6.7\%$  and  $9.7 \pm 4.5\%$  inhibition of the conversion at  $100 \mu\text{M}$ , respectively (Fig. 2d). Thus, compound 3 showed the highest selectivity for 3MST. Next, we applied compound 3 to 3MST-overexpressing COS7 cells to examine its suitability for live cell experiments. 3MST activity in living cells was almost completely suppressed by  $1 \mu\text{M}$  3, demonstrating that 3 is cell-membrane permeable and should be suitable for use in biological studies (Fig. 2e,f).

**X-Ray crystal structure determination of 3MST-inhibitor complexes.** We determined the crystal structures of the m3MST complexes with 1 and 3 at high resolution (Supplementary Table S3). The most remarkable feature is that C248 is persulfurated in both crystal structures (Fig. 3a,b). Persulfurated C248 appears to interact with the 4-pyrimidone-like aromatic ring of both compounds (Fig. 3b). To our knowledge, this interaction is novel in terms of both the long distance ( $>3.45 \text{ \AA}$ ) and the orientation of the persulfide bond (almost perpendicular to the aromatic ring of the inhibitors). Direct hydrogen bonding by R188 and S250 and water-mediated hydrogen bonding by E195 and R197 are commonly observed with compounds 1 and 3. In addition, compound 1 forms water-mediated hydrogen bonds with D63 and H74. Both compounds were in van der Waals contact with W36, L38, P39, D73, H74, Y108, R188, P196, R197, G249, S250, V252 and V277. The thiophene ring (compound 1) and naphthalene ring (compound 3) exhibit cation- $\pi$  interaction with R197 and parallel stacking interaction with the salt bridge between D73 and R197<sup>26</sup>.

**Figure 4. Molecular orbital calculation of interaction energy between persulfided cysteine residue and inhibitors.** (a) Interaction energy calculation of model compounds by CCSD-T/AUG-CC-PVDZ. Calculated interaction energy was  $-10.4 \text{ kcal/mol}$  and this interaction is highly stabilized. (b) Charge distribution of model persulfided molecule and pyrimidone structure. Strong electrostatic interaction was observed between these model molecules. (c) The putative enzymatic reaction mechanism of 3MST (the ping-pong mechanism) is shown. Persulfide or  $\text{H}_2\text{S}$  is generated from 3MP via 3MST. The inhibitor found in this study blocks the second step of the enzymatic reaction, i.e., the transfer of a sulfur atom from the persulfurated cysteine residue at active site to a sulfur acceptor.

To examine the importance of the persulfurated Cys residue, we further performed ITC measurement to determine the dissociation constant  $K_d$  between 3MST and compounds **1** and **3**. Heat release was detected during mixing of the inhibitor and persulfurated 3MST, and the dissociation constants were calculated to be  $3.0 \mu\text{M}$  (compound **1**) and  $0.5 \mu\text{M}$  (compound **3**) (Fig. 3c, left). The persulfurated or non-persulfurated 3MST is the treated or non-treated 3MST with the substrate, 3MP, respectively (The details are described in Methods). The Cys248 existed as un-persulfurated form in crystal structure of 3MP-untreated 3MST (data not shown). In contrast, no heat release or UV-vis absorption change (data not shown) was observed when non-persulfurated 3MST was used (Fig. 3c, right). Thus, it is considered that the persulfurated C248 residue of 3MST is necessary for stable complexation with the inhibitors.

### Computational insight into the interaction between the pyrimidone ring and persulfurated cysteine residue.

We performed theoretical calculations to examine the interaction of the pyrimidone structure of the inhibitors and the persulfurated cysteine residue of 3MST, using high-level coupled-cluster calculation (CCSD(T)) combined with a large aug-cc-pVDZ basis set. The model pyrimidone and  $\text{S-S}^-$  molecules were positioned based on the X-ray crystal structure (Fig. 4a). Although crystallographic structures sometimes exaggerate electrostatic interactions, these structures were considered to be a reasonable starting point for consideration of the unprecedented interaction. Gas-phase calculations indicated that the interaction of  $\text{S-S}^-$  with pyrimidone is strongly exothermic ( $10.4 \text{ kcal/mol}$ ; CCSD(T)/aug-cc-pVDZ), which is not inconsistent with the experimental ITC measurements (Fig. 3c;  $\Delta H = -9.37$  and  $-11.76 \text{ kcal/mol}$  for compounds **1** and **3**, respectively). The stabilization energy is very large compared to hydrogen bonds involving amino acids (ca.  $1-5 \text{ kcal/mol}$ )<sup>27</sup>. To understand this strong interaction, we then performed NBO (Natural Bond Orbital) analysis of the donor-acceptor interaction between the  $\text{S-S}^-$  and the pyrimidone moiety. The  $\text{S-S}^-$  residue is regarded as a potent nucleophile, because the  $\text{S}^-$  anion is strongly activated by the  $\alpha$ -effect of the lone pair of the adjacent sulfur atom. Indeed, the persulfurated cysteine residue is highly reactive and nucleophilic addition occurs with various electrophilic moieties (molecules). However, NBO analysis of the complex indicated no large stabilization interactions ( $<1 \text{ kcal/mol}$ , Supplementary Table S4 and Table S5), because the distance between the  $\text{S}^-$  atom and the pyrimidone ring is too far for orbital interactions. We concluded that the interaction is predominantly due to electrostatic attraction between the persulfur anion and the positively charged carbonyl carbon of the pyrimidone structure (Fig. 4b).

### Discussion

To date, no specific inhibitor of 3MST has been reported. However, application of our recently developed  $\text{H}_2\text{S}$ -selective fluorescent probe for HTS of a large chemical library enabled us to discover several inhibitors. Notably, inhibitors **1** and **3** do not bind to non-persulfurated 3MST, but bind to an intermediate persulfurated

3MST as determined by ITC and X-ray crystallographic analysis. Thus, we concluded that both compounds inhibit the sulfur transfer reaction from the persulfurated intermediate by blocking the binding of the sulfur acceptor to 3MST (Fig. 4c). 3MST has recently been reported to produce not only  $H_2S$ , but also  $H_2S_n$ <sup>9</sup>, and our inhibitors also block the production of  $H_2S_n$  by 3MST (Fig. 2e). It has been suggested that 3MST catalyzes the cleavage of a carbon-sulfur bond and the transfer of a sulfur atom from 3MST to any of a variety of thiophiles, including thiols, cyanides, sulfite, and sulfonates via a sequential mechanism, i.e., the mechanism of the catalysis has been mostly presumed to be a double displacement via the ternary complex of 3MST, 3MP and thiophiles unlike rhodanase<sup>28,29</sup>. Our crystal structure determination shows that the 3MP-binding site of 3MST is too small to allow simultaneous binding of 3MP and a thiol, and the 3MST-inhibitor complexes contained the inhibitor without pyruvate (metabolite of 3MP), presumably because the pyruvate was released from 3MST before the inhibitor binds. Thus, our work provides the experimental support that enzymatic catalysis of 3MST with 3MP proceeds via a ping-pong mechanism, like NAD(P)H-related enzymatic reactions<sup>30</sup>; i.e., the mechanism of the catalysis is a double displacement involving initial formation of the sulfur-substituted (persulfurated cysteine residue-containing) enzyme, as well as rhodanase (Fig. 4c).

It has been reported that the Michaelis constant  $K_m$  of 3MP for 3MST is 4.08 mM<sup>15</sup> and this affinity is relatively weak. Some 3MP(substrate)-like inhibitors of 3MST, such as pyruvate and 3-mercaptopyruvic acid, also show inhibition constant  $K_i$  values of several mM<sup>15,17</sup>. Nevertheless, in this study, we discovered several relatively potent inhibitors of 3MST with  $K_d$  of  $\mu$ M order, and we concluded that this was due to a strong electrostatic interaction between inhibitor and the persulfurated cysteine residue. X-Ray studies have shown that some other enzymes contain a per/polysulfurated cysteine residue in the active site<sup>31-37</sup>, so the findings in this study may also be useful for the molecular design of inhibitors targeting these enzymes.

Our computations indicated that the strong interaction between the persulfurated cysteine residue and the pyrimidone-like structure of the inhibitors is electrostatic in nature. This idea is consistent with the relatively long distance between the two moieties, and is also supported by the calculated interaction energy  $\Delta E$  between the lone pairs of the sulfur atom and the LUMO of the pyrimidone moiety. Some groups have reported aromatic-thiol  $\pi$ -type hydrogen bonding<sup>38,39</sup>, but the calculated  $\Delta E$  between the lone pairs of the sulfur atom and the LUMO of the pyrimidone moiety is too small, ruling this out in the present case. We suspect that this interaction is very sensitive to the orientation of the two lone electron pairs on the sulfur atom relative to the  $\pi$  electron cloud of the aromatic ring, so that interaction configurations that provide significant bonding energy exist only within a narrow configurational space. Thus, in our best knowledge, this strong interaction has never been observed before.

m3MST and human 3MST (h3MST) share high sequence identity (84.5%; 251/297 amino acids). m3MST has two rhodanase-like domains (residues 1-138 and 165-297, according to h3MST numbering<sup>40</sup>) (Supplementary Fig. S11), and the active site is positioned between them. The overall structure of m3MST in the complexes is quite similar to that of h3MST (r.m.s.d. 0.62-0.84 Å) (PDB ID: 3OLH, 4JGT)<sup>40</sup>, but there are several differences between m3MST and h3MST in the active site (Supplementary Fig. S12). One is the position of R197. The side chain of R197 of h3MST is positioned inside the active site and forms a hydrogen bond with pyruvate, whereas that of m3MST-inhibitor complexes is directed outside of the active site and forms a hydrogen bond with D73. The arginine residues in the substrate binding site have been reported to be critical residues in determining substrate specificity for 3MST<sup>41</sup>, and this difference may be due to the binding molecule, i.e., compound **3** and pyruvate. Other side chains are also located at somewhat different positions. Therefore, it is likely that the chemical structures of compounds **1** and **3** will need to be tuned to create selective inhibitors of h3MST.

In summary, we constructed an HTS system with easy-to-use fluorescence detection, utilizing our selective fluorescent probe for  $H_2S$ , HSip-1, and discovered several selective inhibitors of 3MST by screening a library of 174,118 compounds. We analyzed the binding mode between the inhibitors and 3MST. Interestingly, the main interaction was an unprecedented electrostatic interaction between the persulfurated cysteine residue of 3MST and the pyrimidone structure of the inhibitors. Persulfurated cysteine can exist in biological environments<sup>7-9</sup>, and crystal structure determination of several enzymes having the persulfurated cysteine residue indicates that in most cases, the residue is positioned in the active site. Therefore, it may be possible to utilize a similar electrostatic interaction in the molecular design of inhibitors for those enzymes as well. The calculated  $pK_a$  of cysteine persulfide is 4.34 and the persulfurated cysteine residue is thought to be in a deprotonated anionic form<sup>42</sup>, which would be consistent with the strong electrostatic interaction found in this study. Further, our analysis of the binding mode between the inhibitors and 3MST has provided the experimental support for the ping-pong enzymatic mechanism of 3MST with 3MP as a substrate. On the other hand, 3MST activity is elevated in human neoplastic cell lines<sup>43</sup> and erythrocytes from patients with polycythemia vera<sup>44</sup>, so selective 3MST inhibitors might have therapeutic value for these diseases. 3MST-knockout mice were recently reported as a model for human mercaptolactate-cysteine disulfiduria<sup>45</sup> and these mice should be a useful tool for investigating the physiological roles of 3MST. The selective 3MST inhibitors discovered in the present study should also be invaluable for *in vitro* and *in vivo* studies along this line.

## Methods

**HEK293 cell culture.** HEK293 cells were cultured in Dulbecco's modified Eagle's medium (DMEM (Wako, 044-29765)) supplemented with 10% (v/v) fetal bovine serum, penicillin (100 units/mL), and streptomycin (100  $\mu$ g/mL) in a humidified incubator under 5%  $CO_2$  in air.

**Preparation of recombinant 3MST.** The constructed m3MST (UniProt ID: Q505N7)/pGEX and pGEX<sup>46</sup> were each transformed into *E. coli* BL21 cells. The transformed *E. coli* cells were grown overnight 1 mL 2  $\times$  YT medium in the presence of 100  $\mu$ g/mL ampicillin (small scale culture) at 37 °C, then diluted with 150 mL of LB medium in the presence of 100  $\mu$ g/mL ampicillin, and cultured to  $OD_{600} \sim 0.9-1.3$  (3MST 1.1 or 1.2, GST 1.0 or 1.3) at 37 °C (large-scale culture). IPTG (final 0.1 mM) was added to the culture medium to induce expression of GST-3MST or GST, and culture was continued for 21 hr at 20 °C. Cells were harvested by centrifugation

(3000 rpm, 4 °C) for 15 min and resuspended in 12.5 mL of D-PBS buffer (2.7 mM KCl, 137 mM NaCl, 1.5 mM  $\text{KH}_2\text{PO}_4$  and 8.1 mM  $\text{Na}_2\text{HPO}_4$ ) supplemented with lysozyme, 1% Triton X, 10 U DNase (Benzonase, Novagen), 1 mM DTT, and 1% protease inhibitor cocktail (Sigma) on ice for 60 min. The lysate was sonicated for 10 sec three times on ice and centrifuged (3000 rpm, 4 °C) for 15 min to obtain the soluble fraction. The supernatant was purified with a GST purification module (GST GraviTrap, GE Healthcare), and desalted with a PD-10 column (GE Healthcare) according to the manufacturer's instructions. The elution buffer was D-PBS. The collected fractions were analyzed by SDS-PAGE (4–20% gradient acrylamide).

**Bradford assay for protein quantification.** Dye reagent was prepared by diluting 1 part dye reagent (Bio-Rad) concentrate with 4 parts Milli-Q water. The solution was filtered through a Millipore Millex-LH 0.45  $\mu\text{m}$  (Millipore) to remove particulates. 10  $\mu\text{L}$  each of standard (BSA) and sample solution were added to 200  $\mu\text{L}$  of diluted dye reagent in a 96-well plate, and vortex-mixed. The plate was incubated at room temperature for 10 min and the absorbance of each well was measured at 595 nm with a microplate reader ( $n = 4$ ).

**3MST inhibitor screening (Primary screening, confirmation test).** High-throughput screening (HTS) was performed with a chemical library (174,118 compounds at 1st screening and 2,417 compounds at confirmation test) from the Drug Discovery Initiative, The University of Tokyo. Screening methods were as follows: first, low-molecular-weight compounds (1 mM DMSO solution, 200 nL) from library plates were diluted with 10  $\mu\text{L}$  of HSip-1 and 3MST solution to 20  $\mu\text{M}$  (2.0% DMSO) with a Multi-Drop Combi (Thermo) (320 compounds ( $n = 1$ ) or 80 compounds ( $n = 4$ )/384-well plate). Next, a solution of 3MP and DTT (10  $\mu\text{L}$ ) was dispensed into the plates (total volume was 20.2  $\mu\text{L}$ ), which were incubated at room temperature for 3 hr. To assay a lot of 384-well plates simultaneously, we set the reaction time to 3 hours. The fluorescence of HSip-1 was measured ( $\lambda_{\text{ex}} = 485 \text{ nm}$ ,  $\lambda_{\text{em}} = 520 \text{ nm}$ ) with a microplate reader (PHERAstar PLUS (BMG LABTECH)). Background control wells (i.e., GST wells instead of GST-3MST,  $n = 16$ ) were also prepared for all plates (see Supplementary Fig. S3).

**Reactivity test toward 3MP and DTT (2nd screening).** Reactivity of the hit compounds toward 3MP and DTT was examined. The final concentration of the compounds was 10 or 50  $\mu\text{M}$ . The assay protocol was as follows: compounds were diluted with HSip-1 solution to 20 or 100  $\mu\text{M}$  solution (10% DMSO) with a Multi-Drop Combi. Next, 3MP and DTT solution (10  $\mu\text{L}$ , final concentrations: 50  $\mu\text{M}$  3MP and 40  $\mu\text{M}$  DTT) was dispensed into the plates (total volume was 20  $\mu\text{L}$ , 5% DMSO), and the plates were incubated at room temperature for 3 hr. The fluorescence of HSip-1 was measured ( $\lambda_{\text{ex}} = 485 \text{ nm}$ ,  $\lambda_{\text{em}} = 520 \text{ nm}$ ) with a microplate reader (PHERAstar PLUS). Background control wells (i.e., no addition wells instead of addition of 3MP and DTT,  $n = 16$ ) were also prepared for all plates.

**3MST inhibitor screening (Titration test).** The dose-dependency of 3MST inhibition by 146 hit compounds from the second screening was examined to determine the  $\text{IC}_{50}$  values. Screening methods were as follows: first, low-molecular-weight compounds (2 mM DMSO stock solution) from library plates (the final concentrations of the compounds were 0.25, 1, 3, 10, 30  $\mu\text{M}$ ) were diluted with HSip-1 and 3MST solution to 20  $\mu\text{M}$  solution (10% DMSO) with a Multi-Drop Combi. Next, a solution of 3MP and DTT (10  $\mu\text{L}$ ) was dispensed into the plates (total volume was 20  $\mu\text{L}$ , 5% DMSO), and the plates were incubated at room temperature for 3 hr. The fluorescence of HSip-1 was measured ( $\lambda_{\text{ex}} = 485 \text{ nm}$ ,  $\lambda_{\text{em}} = 520 \text{ nm}$ ) with a microplate reader (PHERAstar PLUS). Background control wells (i.e., GST wells instead of GST-3MST,  $n = 16$ ) were also prepared for all plates.

**Reactivity test toward  $\text{H}_2\text{S}$  (3rd screening).** Reactivity of the hit compounds toward  $\text{H}_2\text{S}$  was next examined. The final concentration of the compounds was 10 or 30  $\mu\text{M}$ . The assay protocol was as follows. Compounds were diluted with HSip-1 and cysteine-activated  $\text{H}_2\text{S}$  donor<sup>22</sup> solution to 20 or 60  $\mu\text{M}$  solution (15.4% DMSO) with a Multi-Drop and a pipette. Next, 2 mM L-cysteine solution (10  $\mu\text{L}$ , final concentration: 1 mM L-cysteine) was dispensed into the plates (total volume was 20  $\mu\text{L}$ , DMSO 7.7%), and the plates were incubated at 37 °C for 1 hr. The fluorescence of HSip-1 was measured ( $\lambda_{\text{ex}} = 490 \text{ nm}$ ,  $\lambda_{\text{em}} = 510 \text{ nm}$ ) with a microplate reader. Background control wells (i.e., no addition wells instead of addition of the cysteine-activated  $\text{H}_2\text{S}$  donor,  $n = 16$ ) were also prepared for all plates.

**Determination of inhibitory activity of hit compounds toward purified m3MST by means of gas chromatography.** 1  $\mu\text{L}$  of 1 mM compound (final 10  $\mu\text{M}$ ) was diluted with 89  $\mu\text{L}$  of 3MST solution (final 3.8  $\mu\text{g}/\text{mL}$ ) or GST solution (2.2  $\mu\text{g}/\text{mL}$ ) in 30 mM HEPES buffer (pH 7.4) in a 30 mL collection vial (Iwaki). 10  $\mu\text{L}$  of 3MP and DTT solution (final concentration: 50  $\mu\text{M}$  3MP and 40  $\mu\text{M}$  DTT) was added to 90  $\mu\text{L}$  of the mixture, then the vial was sealed with parafilm and incubated at room temperature for 3 hr. After addition of 200  $\mu\text{L}$  of 1 M sodium citrate buffer (pH 6.0), the mixture was incubated at 37 °C for at least 10 minutes with shaking on rotary shaker to quench the enzymatic activity and facilitate release of  $\text{H}_2\text{S}$  gas from the aqueous phase. A 2 mL sample of head-space gas (total, approximately 29.5 mL) was applied to a gas chromatograph (ODSA-P2, Alpha M.O.S. Japan). The concentrations of  $\text{H}_2\text{S}$  were determined from a standard curve obtained with 0 to 4 nmol of  $\text{Na}_2\text{S}$ , which is a source of  $\text{H}_2\text{S}$ . The protocol is illustrated in Supplementary Fig. 9.

**Transient transfection of HEK 293 cells.** Transient transfection of HEK 293 cells was performed with *TransIT-LT1* (Takara). For transfection, 14  $\mu\text{g}$  of expression plasmid (3MST/pCI)<sup>9</sup> was mixed with 45  $\mu\text{L}$  of *TransIT-LT1* in 1.5 mL of Opti-MEM (Invitrogen) and then added to HEK 293 cells at 60–70% confluency in a 9 cm dish. Cells were harvested at 48 h post-transfection and washed with ice-cold PBS. After precipitation by centrifugation, cell pellets were resuspended in the ice-cold buffer and sonicated.

**Determination of inhibitory activity of the lysate of m3MST-overexpressing cells by means of gas chromatography.** HEK 293 cells in ice-cold isolation buffer containing 30 mM HEPES buffer (pH 7.4), 100  $\mu$ M DTT and 1% protease inhibitor cocktail (Sigma, Japan) were sonicated for 10 sec twice in an Astrason 4000 sonicator (MISONIX, USA) to obtain the lysate. Protein concentration was determined by use of the Bio-Rad Bradford Protein Assay (Bio-Rad Laboratories) according to the manufacturer's instructions. The enzyme reaction was performed as reported, with some modifications<sup>46,47</sup>. 1  $\mu$ L of 10 mM compound (final 100  $\mu$ M) was diluted with 89  $\mu$ L of lysate in a 30 mL collection vial (Iwaki). 10  $\mu$ L of a mixture of 1 mM 3MP (final 100  $\mu$ M) and 100  $\mu$ M DTT was added to 90  $\mu$ L of the cell lysate, and the vial was sealed with parafilm and incubated at 37 °C for 15 min. After addition of 200  $\mu$ L of 1 M sodium citrate buffer (pH 6.0), the mixture was incubated at 37 °C for at least 10 minutes with shaking on a rotary shaker to quench the enzymatic activity and facilitate the release of H<sub>2</sub>S gas from the aqueous phase. A mixture of 1 mL of head-space gas (total, approximately 29.5 mL) and 1 mL of air was applied to a gas chromatograph (ODSA-P2, Alpha M.O.S. Japan). The concentrations of H<sub>2</sub>S were determined from a standard curve obtained with 0 to 8 nmol of Na<sub>2</sub>S, which is a source of H<sub>2</sub>S.

**Construction of rat CSE-HA and rat CBS expression plasmids.** Rat CSE or CBS cDNA<sup>7</sup> was digested with restriction enzymes (XhoI/NotI for CSE, EcoRI/NotI for CBS) and ligated into the XhoI/NotI (CSE) or EcoRI/NotI (CBS) site of the pGEX-6P vector (GE Healthcare) using a Rapid DNA Ligation Kit (Roche Applied Science). The nucleotide sequences of rCSE-HA and rCBS were confirmed by use of an Applied Biosystems 3130 Genetic Analyzer.

**Expression and purification of recombinant rat CSE-HA and rat CBS-HA.** GST-tagged rat CSE-HA or rat CBS-HA was expressed in *E. coli* DH5 $\alpha$  as follows. *E. coli* DH5 $\alpha$  transformed with the pGEX-rCSE-HA or pGEX-rCBS-HA plasmid was cultured overnight in LB medium containing 100  $\mu$ g/mL ampicillin (and 0.3 mM 5-aminolevulinic acid, for CBS) at 37 °C, and the 120 mL culture was inoculated into 2400 mL of LB medium. Further growth of the culture was performed at 37 °C with vigorous shaking until OD<sub>600</sub> reached 0.8. IPTG was added to the *E. coli* DH5 $\alpha$  culture at a final concentration of 0.1 mM and incubation was continued at 18 °C. After 24 h, *E. coli* DH5 $\alpha$  was collected by centrifugation, washed with cold TBS, and lysed in 120 mL of purification buffer (50 mM Tris-HCl pH7.5, 150 mM NaCl, 0.2 mM EDTA, 0.2 mM EGTA, 0.5 mM PMSE, 1 mM DTT) by adding 1 mg/mL lysozyme, 1% Triton X-100 (final concentration), and 50 units TurboNuclease (Nacalai Tesque) on ice for 1 h followed by sonication. After centrifugation at 15000  $\times$  g for 60 min, the supernatant was applied to a 2 mL of COSMOGEL GST-Accept (Nacalai Tesque) and washed with 30 mL of purification buffer. The fusion protein was cleaved on the column with 800  $\mu$ L of purification buffer containing 40 units of Turbo3C Protease (Nacalai Tesque) for 15 h at 4 °C. The pass-through fraction was collected and stored at -30 °C after addition of an equal volume of a solution containing 80% glycerol and 20% ethylene glycol.

**Determination of inhibitory activity towards purified CBS by means of gas chromatography.** 1  $\mu$ L of 10 mM compounds (final 100  $\mu$ M) was diluted with 89  $\mu$ L of CBS solution (final 16.4  $\mu$ g/mL) in 30 mM HEPES buffer (pH 7.4) containing PLP (final 50  $\mu$ M) and SAM (final 100  $\mu$ M) in a 15 mL centrifuge tube. 10  $\mu$ L of L-cysteine and DL-homocysteine solution (final 10 mM L-cysteine and DL-homocysteine) was added to 90  $\mu$ L of the mixture, then the tube was sealed with parafilm and incubated at 37 °C for 15 min. After addition of 200  $\mu$ L of 1 M sodium citrate buffer (pH 6.0), the mixture was incubated at 37 °C for at least 10 minutes with shaking on a rotary shaker to quench the enzymatic activity and facilitate the release of H<sub>2</sub>S gas from the aqueous phase. A 600  $\mu$ L sample of head-space gas (total, approximately 14.5 mL) was applied to a gas chromatograph equipped with a flame photometric detector and a data processor C-R8A Chromatopac (Shimadzu). The concentrations of H<sub>2</sub>S were determined from a standard curve obtained with 0 to 5 nmol of Na<sub>2</sub>S, which is a source of H<sub>2</sub>S.

**Determination of inhibitory activity towards purified CSE by means of gas chromatography.** 1  $\mu$ L of 10 mM compounds (final 100  $\mu$ M) was diluted with 89  $\mu$ L of CSE solution (final 6.0  $\mu$ g/mL) in 30 mM HEPES buffer (pH 7.4) containing PLP (final 50  $\mu$ M) in a 15 mL centrifuge tube. 10  $\mu$ L of L-cysteine solution (final 10 mM L-cysteine) was added to 90  $\mu$ L of the mixture, then the tube was sealed with parafilm and incubated at 37 °C for 15 min. After addition of 200  $\mu$ L of 1 M sodium citrate buffer (pH 6.0), the mixture was incubated at 37 °C for at least 10 minutes with shaking on rotary shaker to quench the enzymatic activity and facilitate the release of H<sub>2</sub>S gas from the aqueous phase. A 1 mL sample of head-space gas (total, approximately 14.5 mL) was applied to a gas chromatograph equipped with a flame photometric detector and a data processor C-R8A Chromatopac (Shimadzu). The concentrations of H<sub>2</sub>S were determined from a standard curve obtained with 0 to 5 nmol of Na<sub>2</sub>S, which is a source of H<sub>2</sub>S.

**Live-cell fluorescence imaging experiment.** COS7 cells, purchased from ATCC (American Type Culture Collection, USA), were cultured in DMEM (Dulbecco's modified Eagle's medium) (Gibco 11885), containing 10% fetal bovine albumin (Invitrogen) and 1% penicillin streptomycin (Invitrogen). Cells were maintained at 37 °C under an atmosphere of 5% CO<sub>2</sub> in air. Transient transfection of COS7 cells was performed with Lipofectamine LTX and PLUS reagents (Invitrogen). As the standard condition, 0.7  $\mu$ g plasmid<sup>9</sup>, 0.7  $\mu$ L PLUS reagent, and 2  $\mu$ L lipofectamine LTX were mixed in 100  $\mu$ L Opti-MEM (Gibco) and 5  $\mu$ L of the mixture was added to the cells (0.2 mL of the medium). Transfection efficiency was confirmed to be 30–45% using pHcRed1-Nuc Vector (Clontech) as a control. COS7 cells seeded on 1  $\mu$ -Slide 8-well IbiTreat (Ibidi) were washed with 200  $\mu$ L of Hanks' Balanced Salt Solutions (HBSS) 18 hr after transfection, and then incubated for 30 min at 37 °C in 200  $\mu$ L DMEM (Gibco 21063) containing 50  $\mu$ M SSP4 (a commercially available fluorescent probe for sulfane sulfur (DOJINDO, Japan)) and 0–10  $\mu$ M inhibitor with 0.6% DMSO and 0.03% Pluronic F127 as a cosolvent. After incubation, cells were washed twice with HBSS and 200  $\mu$ L DMEM (Gibco 21063) containing 0–10  $\mu$ M inhibitor with 0.1% DMSO as a cosolvent was added. Incubation was continued in DMEM containing 500  $\mu$ M 3-mercaptopyruvate (3MP)

for 10 min at 37 °C. Fluorescence images were captured using a Leica Application Suite Advanced Fluorescence (LAS-AF) with a TCS SP5 and a 40× objective lens. The light sources were an argon laser and white light laser. The excitation wavelengths were 488 nm and 591 nm. The emission wavelengths were 500–540 nm for SSP4 (PMT; Gain: 1000) and 600–650 nm for RFP (HyD; Gain: 100).

**Gene expression and protein purification for ITC analysis and X-ray crystallography.** The recombinant full-length wild-type mouse 3MST and mutant m3MST (C65S/C255S/C264S) were expressed as an N-terminal His-tagged protein (MGSSHHHHHSSGLEVLFGPGS-3MST) in *E. coli* JM109 (DE3). The pET44a(+) vector (Novagen) was used as an expression vector. Cells were grown at 37 °C in LB broth (Miller) or 2 × YT broth containing 0.1 g/L ampicillin to OD<sub>600</sub> about 0.5, and then protein expression was induced by adding IPTG (final conc. 0.5 mM (LB), 1 mM (2 × YT)). Cells were cultured overnight at 18–20 °C with shaking and harvested at 4 °C by centrifugation at 9,000 rpm for 5 min. Harvested cells were resuspended in lysis buffer containing 0.1 M HEPES-NaOH pH 8, 0.5 M NaCl, 0% or 10% glycerol, 0.5 mM TCEP, 1 mM PMSE, and 1% EtOH, and disrupted by sonication. Cell lysis solutions were centrifuged at 20,000 rpm for 20 min. Mouse 3MST proteins were affinity-purified on cOmplete His-Tag Purification Resin (Roche) using buffer containing 0.02 M HEPES pH 8, 0.15 M NaCl, 10% glycerol, 0.5 mM TCEP, 0–0.25 M imidazole. The proteins were further purified on HisTrap HP (GE Healthcare) by increasing the imidazole concentration in buffer containing 0.02 M HEPES pH 8, 0.15 M NaCl, 10% glycerol, and 0.05 mM TCEP until proteins were eluted. Then the His-tag was removed by GST-fusion HRV 3C protease digestion. The proteins were further purified by anion exchange chromatography on a HiTrap Q HP (GE Healthcare) by increasing the NaCl concentration in buffer containing 0.02 M HEPES pH 8, 10% glycerol, 0.5 mM TCEP until proteins were eluted, and then by gel filtration chromatography on Superdex 75 prep grade using buffer containing 0.02 M HEPES pH 7.5, 0.3 M NaCl, 0.5 mM TCEP. Wild-type 3MST was used in ITC analysis and mutant 3MST was used for crystallization.

**ITC analysis.** Persulfurated 3MST was prepared as follows: 3MST-3MP solution (5 μM 3MST, 25 μM 3MP, 20 μM TCEP, 0.02 M glycine-NaOH pH9, 0.1 M NaCl) was incubated for 2 hr at room temperature. To prevent buffer mismatch and to remove unreacted 3MP and reaction product (pyruvate), the reaction solution was exchanged to ITC measurement solution (0.02 M glycine-NaOH pH 9, 0.1 M NaCl, 5% DMSO) using an Amicon Ultra (10 K) (Millipore) or Vivaspin (10 K) (Sartorius). Non-persulfurated 3MST solution was also prepared by buffer exchange. Both inhibitors were dissolved in the ITC measurement solution. Inhibitor solution (0.5 mM compound 1 or 0.25 mM compound 3) were titrated into a protein solution (0.05 mM 3MST) at 25 °C using a MicroCal iTC200 (GE Healthcare). The first injection of 0.4 μL was followed by 18 injections of 2 μL with 150 s between each injection. Each experiment was repeated three times ( $n = 3$ ). For data analysis, the first injection peak was removed. Data analyses and curve fitting to a single-site binding model were performed by Origin7 SR4 software (OriginLab).

**Crystallization and structure determination.** The concentrations of protein-inhibitor complexes during crystallization could not be precisely determined because we did not evaluate the inhibitor binding rate, so the following final concentrations are estimated values. 3MST-compound 1 complex was prepared as follows. Protein-compound 1 solution (0.08 mg/mL or 0.17 mg/mL 3MST, 10 μM compound 1, 50 μM 3MP, 0 μM or 40 μM TCEP, 0.03 M glycine-NaOH pH 9, 0.1 M NaCl, 1% DMSO) was incubated overnight at 25 °C. The m3MST-compound 1 complex solution was exchanged to a crystallization solution (0.02 M glycine-NaOH pH 9, 0.3 M NaCl) and concentrated to about 10–30 mg/mL using an Amicon Ultra (10 K). 3MST-compound 3 complex was prepared as follows. Protein-compound 3 solution (0.08 mg/mL 3MST, 10 μM compound 3, 50 μM 3MP, 40 μM TCEP, 0.03 M HEPES-NaOH pH 8.2, 0.1 M NaCl, 1% DMSO) was incubated overnight at 25 °C. The 3MST-compound 3 complex solution was also exchanged to a crystallization solution (0.02 M HEPES-NaOH pH 8.2, 0.3 M NaCl) and concentrated to about 10–30 mg/mL using an Amicon Ultra (10 K). Crystals were grown at 4 °C by the sitting-drop vapor diffusion method by mixing protein-inhibitor complex solution and reservoir solution (36% (w/v) PEG 3,350, 0.1 M HEPES-NaOH pH 8.1) in a volume ratio of 4:1, and equilibrating the samples against 50 μL of reservoir solution. Crystals of 3MST-compound 3 complex often appeared in or around precipitates that were generated during preparation of the complex. The crystals used for data collection were cryo-cooled in liquid nitrogen using reservoir solution as a cryoprotectant. X-Ray diffraction data were collected at 100 K at the PF/KEK BL5A beamline and at the SPring-8 BL44XU beamline. Diffraction data were integrated and scaled using the program HKL2000 (HKL Research, Inc.)<sup>48</sup>. The initial phases were determined by molecular replacement with the program Molrep<sup>49</sup> using h3MST (PDB ID: 3OLH) or the determined m3MST structure as a search model. Model buildings were performed with the program WinCOOT<sup>50,51</sup>. Structural refinements were performed with the programs Refmac<sup>52,53</sup> and PHENIX<sup>54</sup>. After several cycles of manual model building and structural refinement, the electron density corresponding to the inhibitor was clearly observed. Chemical structures of both inhibitors were drawn using ChemSketch<sup>55</sup> (Advanced Chemistry Development, Inc. (ACD/Labs)), and then regularization and chemical restraint parameters for structural refinement were generated using JLigand<sup>56</sup>. 3MST-compound 1 complex was refined using intensity-based twin refinement with anisotropic temperature factors for non-hydrogen atoms. The geometry of the structure was verified using the PROCHECK program<sup>57</sup>. Coordinates and the structure factors were deposited in the Protein Data Bank (PDB code: 5WQJ and 5WQK).

**Calculation methods.** All calculations were performed with the Gaussian 09 program system (Revision D.01)<sup>58</sup>. Single-point energy was calculated in the gas phase based on the single crystal structure at the CCSD(T) level<sup>59</sup> with the aug-cc-pVDZ basis set<sup>60,61</sup>. NBO (Natural Bond Orbital) calculation was performed at the same level with the NBO 3.1 package in the Gaussian 09 program.

## Acknowledgements

This work was supported in part by grants from MEXT (Specially Promoted Research Grant Nos 22000006 to T.N., Grant Nos 24689003, 16H05099 and 16H00823 to K.H., Grant Nos 15K05529 and 16J01710 to T.T.), and SENTAN, JST to K.H., who was also supported by Mochida Memorial Foundation for Medical and Pharmaceutical Research, The Asahi Glass Foundation, Takeda Science Foundation and The Naito Foundation. K.S. was supported by a Grant-in-Aid for JSPS Fellows. This work was also supported by JSPS KAKENHI Grant-in-Aid for Young Scientists B Grant Number 15K18994 to Y.T. and Program for the Strategic Research Foundation at Private Universities to Y.W., as well as by Platform for Drug Discovery, Informatics, and Structural Life Science from the Ministry of Education, Culture, Sports, Science and Technology, Japan. Computational resources were generously allotted (Projects G15011) at RICC (RIKEN Integrated Cluster of Clusters) and HOKUSAI GreatWave, RIKEN. This work was partly supported by JSPS KAKENHI Scientific Research (S) (No. 24229001 (to M.U.)), and JSPS TEI-SOKU Program (PU14008) (to C.W.). This research was also supported by The Uehara Memorial Foundation, Kobayashi International Scholarship Foundation, and The Asahi Glass Foundation (to M.U.). A part of this work was performed using synchrotron beamline BL44XU at SPring-8 under the Cooperative Research Program of the Institute for Protein Research, Osaka University (2014A6933 and 2014B6933).

## Author Contributions

K.H. and T.N. planned the experiments and wrote the manuscript. K.S., K. Shimamoto and Y.T. performed the screening and selectivity experiments. Y.S., S.T. and T.S. performed the X-ray crystallography analysis and the ITC analysis. C.W. and M.U. performed the calculations. T.T., T.K. T.U. and Y.U. advised on the experiments. T.O. and H.K. designed the high-throughput screening. N.S., Y.O., Y.T., Y.W. and H.K. performed the enzymatic assays and advised on the experiments. K.S., K.H. and T.N. planned the project. All authors edited the manuscript.
