Bulleyaconitine (BAA) has been shown to possess antinociceptive activities by stimulation of dynorphin A release from spinal microglia. This study investigated its underlying signal transduction mechanisms. The data showed that (1) BAA treatment induced phosphorylation of CREB (rather than NF- κ B) and prodynorphin expression in cultured primary microglia, and antiallodynia in neuropathy, which were totally inhibited by the CREB inhibitor KG-501; (2) BAA upregulated phosphorylation of p38 (but not ERK or JNK), and the p38 inhibitor SB203580 (but not ERK or JNK inhibitor) and p38 β gene silencer siRNA/p38 β (but not siRNA/p38 α) completely blocked BAA-induced p38 phosphorylation and/or prodynorphin expression, and antiallodynia; (3) BAA stimulated cAMP production and PKA phosphorylation, and the adenylate cyclase inhibitor DDA and PKA inhibitor H-89 entirely antagonized BAA-induced prodynorphin expression and antiallodynia; (4) The Gs-protein inhibitor NF449 completely inhibited BAA-increased cAMP level, prodynorphin expression and antiallodynia, whereas the antagonists of noradrenergic, corticotrophin-releasing factor, A1 adenosine, formyl peptide, D1/D2 dopamine, and glucagon like-peptide-1 receptors failed to block BAA-induced antiallodynia. The data indicate that BAA-induced microglial expression of prodynorphin is mediated by activation of the cAMP-PKA-p38 β -CREB signaling pathway, suggesting that its possible target is a Gs-protein-coupled receptor – “aconitine receptor”, although the chemical identity is not illustrated.

The antinociceptive effects of the *Aconitum* extracts have been demonstrated in a variety of experimental pain studies, such as the tail-pressure, paw-pressure, tail-flick, and hot-plate tests, acetic acid writhing, repeated cold stress pain, adjuvant-induced arthritic pain, streptozotocin-induced diabetes pain, and peripheral nerve injury-induced neuropathic pain^{1–5}. It is evident that the antinociceptive effects of *Aconiti* were mediated by the pharmacological action of diterpenoid alkaloid and to date, there are approximately 170 diterpenoid alkaloids identified, including aconitine, bulleyaconitine A, mesaconitine, hypaconitine, bullatine A, and lappaconitine, which could be mainly classified into three skeletal categories, i.e., C₁₈-, C₁₉-, and C₂₀-diterpenoid alkaloids^{6,7}. Bulleyaconitine A (BAA), a C₁₉-diterpenoid alkaloid isolated from *Aconitum bulleyanum*, is marketed in China to treat chronic pain and rheumatoid arthritis⁸. Earlier studies demonstrated that systemic BAA administration blocked acetic acid-induced writhing response and formalin-induced tonic hyperalgesia⁸. A recent study further demonstrated that subcutaneous and intrathecal administration of BAA and its analog aconitine markedly attenuated peripheral spinal nerve ligation- and paclitaxel-induced neuropathic pain and cancer cell inoculation-induced bone pain, in addition to its inhibition of formalin-induced tonic pain, although they did not reduce formalin-induced acute flinching response^{9,10}. Moreover, bullatine A, a C₂₀-diterpenoid alkaloid, significantly attenuated pain hypersensitivity, including mechanical allodynia and thermal hyperalgesia in a variety of rodent models of pain, such as peripheral neuropathy, bone cancer pain, streptozotocin diabetes-induced pain, formalin-induced tonic pain, and complete Freund's adjuvant-induced rheumatic inflammatory pain¹¹. The antinociceptive activity was also demonstrated in lappaconitine, a C₁₈-diterpenoid alkaloid, in neuropathy and bone cancer pain¹².

It has been generally accepted that interaction of BAA and their analogs with neuronal voltage-gated sodium channels promoted aconitines antinociception and mediated their toxicity^{7,13,14}, but a novel analgesic mechanism

King's Lab, Shanghai Jiao Tong University School of Pharmacy, 800 Dongchuan Road, Shanghai 200240, China. Correspondence and requests for materials should be addressed to Y.-X.W. (email: yxwang@sjtu.edu.cn)

involving release of spinal microglial dynorphin A and subsequent activation of neuronal κ -opioid receptors have been also recently proposed^{9–11}. It was initially discovered by a Japanese group showing that the processed *Aconiti* tuber antinociception in a mouse nociceptive model of repeated cold stress was eliminated by intrathecal injection of the dynorphin A antibody and the κ -opioid receptor antagonist NBI^{3–5}. The King's Lab in China further confirmed that (i) the dynorphin A antibody and κ -opioid receptor antagonism (NBI and GNTI) in neuropathy eliminated antinociceptive effects of the purified active ingredients and their metabolites of *Aconiti*, including BAA⁹, bullatine A¹¹, lappaconitine¹², aconitine and benzoyleconitine¹⁰; (ii) the active ingredients and their metabolites of *Aconiti* could stimulate dynorphin A expression and secretion from the spinal cords of neuropathic rats^{9–11}; (iii) The stimulated dynorphin A expression was specifically derived from spinal microglia but not neurons or astrocytes, identified by the cellular chemistry assay, double immunofluorescence staining technique, and application of the microglia inhibitor minocycline. However, activation of spinal microglia was not required for aconitines to express dynorphin A, as aconitines, for similar degrees, stimulated dynorphin A expression in both contralateral/sham and ipsilateral spinal dorsal horn, and cultured primary microglia both in the presence and absence of lipopolysaccharides treatment^{9–12}; (iv) Aconitines antinociception was separated from neurotoxicity, demonstrated by the inability of the sodium channel blockers lidocaine and ropivacaine on dynorphin A expression and BAA-stimulated dynorphin A expression, and inability of minocycline on BAA-induced acute neurotoxicity⁹. Taken together, all these data suggest that aconitines, including BAA, produced antinociception in pain hypersensitivity states specifically through dynorphin A expression and secretion from spinal microglia, but not through their counteractions with neuronal voltage-gated sodium channels. It is known that dynorphin A is an endogenous κ -opioid receptor agonist, distributes throughout the central nervous system, localized and secreted in neurons, astrocytes, and microglia^{9,15,16}, and serves multiple regulatory functions, such as analgesia, psychomimesis, dysphoria, diuresis, and antipruritic effects¹⁷, in the central nervous system.

G-protein-coupled receptors (GPCRs) constitute the largest family of cell surface proteins for cell signal transduction. G-proteins are heterotrimeric signaling molecules composed of α , β and γ subunits, and are divided into four major classes, i.e., Gs, Gi, Gq and G₁₂, on the basis of amino acid similarities of their α -subunits¹⁸. Although such a classification is rather arbitrary, there is a general mechanism among the members of the subfamily. Stimulation of the Gs subfamily activates adenylyl cyclase and stimulates accumulation of a diffusible second messenger cyclic AMP (cAMP) and activation of cAMP-activated protein kinase A (PKA)¹⁹. The activated form of PKA in turn induces phosphorylation of a large variety of the downstream target proteins, including transcription factors like the cAMP response element-binding protein (CREB) and NF- κ B, to ultimately regulate numerous cell events²⁰. Serine 133 is a well-characterized CREB phosphorylation site and can be phosphorylated by PKA and the cAMP-PKA/CREB signaling can be initiated as a classical pathway²¹. An alternative pathway of the mitogen-activated protein kinase (MAPK)/CREB is also later proposed after the observation that CREB phosphorylation can also be induced by p38 MAPK on the same serine 133 site²². It is known that CREB is able to induce the transcription of the dynorphin A precursor prodynorphin gene in neurons^{22,23}. Therefore, this study aimed to systemically investigate signal transduction pathways involving CREB activation for aconitines represented by BAA to upregulate prodynorphin expression in microglia.

Results

CREB activation mediates BAA-induced prodynorphin expression in primary microglia. We first assessed the stimulatory effects of BAA on phosphorylation of the transcription factors CREB and NF- κ B in primary cultures of microglia. Incubation of 1 μ M of BAA for 1 hour induced a robust increase in CREB phosphorylation by 62%, measured by Western blot, compared to the control group ($P < 0.05$ using unpaired and two-tailed Student's *t*-test; Fig. 1A). In contrast, the same BAA concentration did not significantly affect NF- κ B p65 phosphorylation (Fig. 1B).

Pretreatment with the specific CREB activation inhibitor KG-501 (25 μ M)²⁴ for 30 minutes did not significantly affect the basal CREB phosphorylation level, whereas BAA treatment (1 μ M) induced CREB phosphorylation by 66%, which was completely inhibited by 30 minute-KG-501 pretreatment ($P < 0.05$ by two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 1C).

Since BAA-increased dynorphin A level measured by the enzyme-linked immunosorbent assay was in parallel with the expression of the cellular prodynorphin gene encoding dynorphin A in spinal microglia from neonatal and adult rats⁹, prodynorphin expression was only measured in this study. Indeed, BAA incubation (1 μ M) of cultured primary microglial cells for 2 hour significantly increased expression of prodynorphin mRNA by 2.3 fold, measured by qRT-PCR. The stimulatory effect of BAA was completely inhibited by KG-501 (25 μ M) pretreatment, although it did not significantly alter the basal prodynorphin expression ($P < 0.05$ using two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 1D).

Furthermore, KG-501 was also given to neuropathic rats induced by tight ligation of spinal nerves. Intrathecal injection of normal saline (10 μ L) or KG-501 (10 μ g)²⁵ did not significantly affect baseline paw withdrawal thresholds in response to mechanical stimulation in both contralateral and ipsilateral paws, whereas intrathecal BAA (300 ng) markedly and time-dependently increased mechanical thresholds in the ipsilateral paws (but not in the contralateral paws) of saline-pretreated rats. BAA mechanical allodynia was totally suppressed by 30 minute-pretreatment of KG-501 ($P < 0.05$ using two-way ANOVA followed by a post-hoc Student-Newman-Keuls test; Fig. 1E).

p38 activation mediates BAA-induced prodynorphin expression in primary microglia. MAPKs are a family of signaling molecules to transduce extracellular stimuli into intracellular responses in a wide variety of circumstances. The MAPK family includes p38, ERK and JNK, and is activated through different upstream transduction chain reactions²⁶. In order to assess whether BAA affected MAPK activation, we measured phosphorylation

Figure 1. Effects of bulleyaconitine A (BAA) on phosphorylation of CREB (A) and NF- κ B (B), and blockade effects of the specific CREB activation inhibitor KG-501 on BAA-induced CREB phosphorylation (C) and prodynorphin expression (D) in primary cultures of microglia, and spinal mechanical antiallodynia (E) in neuropathic rats. Primary microglial cells were collected from the spinal cord of 1-day-old neonatal rats. For the CREB and NF- κ B phosphorylation, 1 μ M BAA was added into primary microglia culture for 1 hour and the levels of phosphorylated CREB and NF- κ B p65 were determined using Western blot. The representative blots are shown in the upper panels of each panel. The dynorphin A precursor prodynorphin mRNA expression was measured using qRT-PCR and normalized to *GAPDH* mRNA. For mechanical antiallodynia, neuropathic rats were induced by tight ligation of L5/L6 spinal nerves and mechanical thresholds were measured in both contralateral and ipsilateral paws. Data are expressed as means $\pm$ SEM ($n = 3$ in each treatment with two independent repeats in cultured primary microglial cells, and $n = 6$ in each group of neuropathic rats). ^{a,b} $P < 0.05$ using the unpaired and two-tailed Student's *t*-test or two-way repeated measures ANOVA followed by the post-hoc student-Newman-Keuls test, compared with the control and BAA groups, respectively.

of p38, ERK and JNK using Western blot. Treatment with 1 μ M BAA in cultured primary microglia for 1 hour significantly induced p38 phosphorylation by 2.5 fold ($P < 0.05$ using the unpaired and two-tailed Student's *t*-test; Fig. 2A). However, the same concentration of BAA failed to activate ERK (Fig. 2B) or JNK (Fig. 2C).

Figure 2. Effects of bulleyaconitine A (BAA) on levels of phosphorylated p38 (A), ERK (B) and JNK MAPK (C), and blockade effects of the specific inhibitors of p38, ERK and JNK on BAA-induced expression of prodynorphin mRNA level (D) in primary cultures of microglia, and spinal mechanical antiallodynia in neuropathic rats (E). Primary microglial cells were collected from the spinal cord of 1-day-old neonatal rats. For phosphorylation, 1 μ M BAA was added into microglia culture for 1 hour and levels of phosphorylated p38, ERK, JNK and CREB were determined by using Western blot. The representative blots are shown in the upper panels of each panel. For gene expression, the MAPK inhibitors were incubated 30 minutes before BAA treatment and primary microglial cells were collected 2 hours later. Expression of the dynorphin A precursor prodynorphin gene was determined using qRT-PCR and normalized to *GAPDH* mRNA. For mechanical antiallodynia, neuropathic rats were induced by tight ligation of L5/L6 spinal nerves, and mechanical thresholds were measured in both contralateral and ipsilateral paws. (F) Blockade effect of the p38 inhibitor SB203580 on BAA-induced CREB phosphorylation in cultured primary microglia. Data are expressed as means $\pm$ SEM ($n = 3$ in each treatment with two independent repeats in cultured primary microglial cells, and $n = 6$ in each group of neuropathic rats). ^{a,b} $P < 0.05$ using the unpaired and two-tailed Student's *t*-test or two-way repeated measures ANOVA followed by the post-hoc student-Newman-Keuls test, compared with the control and BAA groups, respectively.

To further determine whether p38 activation was causally associated with BAA-stimulated prodynorphin expression, the selective p38 inhibitor SB203580, ERK inhibitor U0126, and JNK inhibitor SP600125 were employed. SB203580 (50 μ M)²⁷, U0126 (50 μ M)^{28,29} and SP600125 (50 μ M)³⁰ treatment did not significantly alter basal levels of prodynorphin expression, whereas 30 minutes SB203580 pretreatment completely blocked 1 μ M BAA-increased prodynorphin expression ($P < 0.05$ using two-way ANOVA followed by a post-hoc Student-Newman-Keuls test). In contrast, neither SP600125 nor U0126 significantly suppressed BAA-increased prodynorphin expression (Fig. 2D).

In neuropathic rats, mechanical thresholds were measured in both contralateral and ipsilateral paws. Intrathecal injection of 10 μ L of normal saline or 10 μ g each of SB203580, U0126 and SP600125^{31–33} did not significantly affect baseline mechanical withdrawal response in either contralateral or ipsilateral paws. In saline-pretreated rats, intrathecal BAA (300 ng) in the ipsilateral paws produced a time-dependent mechanical allodynia, which was completely prevented by the 30 minutes SB203580 pretreatment ($P < 0.05$ using two-way ANOVA followed by a post-hoc Student-Newman-Keuls test), but not with U0126 and SP600125 (Fig. 2E).

We further assessed the p38-dependency of BAA-induced CREB phosphorylation. Treatment with SB203580 (50 μ M) did not significantly affect the basal levels of CREB phosphorylation, but nearly completely inhibited BAA (1 μ M)-upregulated CREB phosphorylation ($P < 0.05$ using two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 2F).

p38 β phosphorylation mediates BAA-induced prodynorphin expression in spinal microglia.

There are four isoforms of p38 MAPK, i.e., α , β , γ , and δ , among which α and β are the major isoforms in the mature nervous system and the targets of most p38 inhibitor drug development^{26,34}. To identify which p38 isoforms mediate BAA-induced prodynorphin expression, p38 α and p38 β expression in cultured primary microglia was specifically silenced using the RNA interference technology. Compared to the nonspecific oligonucleotide control, transfection with siRNA/p38 α (0.4 μ M) for 5 hours significantly reduced p38 α mRNA expression by 62%, measured by qRT-PCR ($P < 0.05$ using one-way ANOVA followed by a post-hoc Student-Newman-Keuls test), whereas it did not significantly affect p38 β mRNA expression (Fig. 3A). Western blot also showed the identical data, i.e., compared to the nonspecific oligonucleotide control, siRNA/p38 α significantly reduced levels of p38 α protein by 66% ($P < 0.05$ using one-way ANOVA followed by a post-hoc Student-Newman-Keuls test), but not p38 β protein levels (Fig. 3B). Furthermore, transfection with 0.4 μ M siRNA/p38 β significantly reduced p38 β mRNA by 64% and p38 β protein by 55%, compared to the nonspecific oligonucleotide control ($P < 0.05$ using one-way ANOVA followed by a post-hoc Student-Newman-Keuls test), but did not affect expression of p38 α mRNA or protein (Fig. 3C,D).

Treatment with 1 μ M BAA for 1 hour significantly induced p38 phosphorylation by 2.3 fold. Pretreatment with siRNA/p38 β (but not siRNA/p38 α) completely inhibited BAA-induced p38 phosphorylation ($P < 0.05$ using two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 3E). However, pretreatment with siRNA/p38 β (but not siRNA/p38 α) completely suppressed BAA-stimulated prodynorphin expression ($P < 0.05$ using two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 3F).

Further studies were undertaken to identify which isoform of p38 mediated BAA-induced spinal mechanical allodynia in neuropathy. Five groups of neuropathic rats received multiple daily intrathecal injections of the vehicle (Dotap, 40 μ g/day), nonspecific siRNA oligonucleotide (5 μ g/day), siRNA/p38 α (5 μ g/day), or siRNA/p38 β (5 μ g/day) for 7 days. The mechanical thresholds in both contralateral and ipsilateral paw were measured each morning before injection. On the eighth day, the rats received a single intrathecal injection of saline (10 μ L for the first vehicle group) or BAA (300 ng for the remaining four groups). Mechanical thresholds were measured once 1 hour after BAA injection. As shown in Fig. 4A, consecutive daily intrathecal injections of siRNA/p38 α and siRNA/p38 β over 7 days did not significantly alter mechanical thresholds in either contralateral or ipsilateral paws, compared with the vehicle or nonspecific siRNA oligonucleotides control groups. On the 8th day, single intrathecal injection of BAA (300 ng) produced marked mechanical allodynia in the ipsilateral paws. Knockdown of p38 β gene using siRNA/p38 β completely prevented BAA mechanical allodynia ($P < 0.05$ using two-way ANOVA followed by the post-hoc Student-Newman-Keuls test), whereas multiple daily injections of siRNA/p38 α was not able to block BAA-induced mechanical allodynia (Fig. 4B).

After completion of the behavior test, all rats were immediately sacrificed and spinal lumbar segments were obtained for later gene and protein assessment. Compared to the nonspecific siRNA oligonucleotides control, multiple daily intrathecal injections of siRNA/p38 α significantly reduced p38 α mRNA level by 51% ($P < 0.05$ using one-way ANOVA followed by post-hoc Student-Newman-Keuls test), but not p38 β mRNA (Fig. 4C). Western blot showed similar data, i.e., siRNA/p38 α significantly reduced p38 α protein expression by 61% ($P < 0.05$ using one-way ANOVA followed by post-hoc Student-Newman-Keuls test), but not p38 β protein (Fig. 4D). In contrast, multiple daily intrathecal injections of siRNA/p38 β significantly reduced p38 β mRNA level by 62% and protein by 50% ($P < 0.05$ using one-way ANOVA followed by post-hoc Student-Newman-Keuls test), but not p38 α mRNA or protein (Fig. 4E,F).

The cAMP-PKA signaling mediates BAA-induced prodynorphin expression in primary microglia.

Primary microglial cells were grown and treated with different BAA concentrations (10^{-10} , 10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} , and 10^{-5} M) for measurement of intracellular cAMP levels using a commercial ELISA kit 30 minutes later. Compared to the control, BAA treatment significantly enhanced the intracellular cAMP level in a concentration-dependent manner, with an EC₅₀ of 40.4 nM (Fig. 5A). BAA-stimulated PKA activation was then determined with Western blot analysis. As shown in Fig. 5B, 1 μ M BAA treatment of cultured primary microglia for 1 hour significantly increased PKA phosphorylation by 58% ($P < 0.05$ using unpaired and two-tailed Student t-test).

Figure 3. Differential effects of siRNA/p38 α and siRNA/p38 β on expression of p38 α (A,B) and p38 β mRNA and protein (C,D), bulleyaconitine A-induced p38 phosphorylation (E) and prodynorphin gene expression (F) in primary cultures of microglia. Primary microglial cells were collected from the spinal cord of 1-day-old neonatal rats. For the gene knockdown, siRNA/p38 α and siRNA/p38 β were transfected into primary microglia for 5 hours and microglia were cultured for additional 24 hours after refreshed the culture medium. Expressions of the mRNA of p38 α , p38 β and prodynorphin and protein of p38 α and p38 β referred to *gapdh* were determined using qRT-PCR and Western blot, respectively. For the phosphorylation assay, primary microglial cells were treated with 1 μ M BAA for 1 hour and then subjected to Western blot analysis of phosphorylated p38 with an anti-phospho-p38 antibody. The representative blots are shown in the upper panels of each panel. Data are expressed as means $\pm$ SEM ($n = 3$ per group in each treatment with three independent repeats). ^{a,b} $P < 0.05$ using one-way or two-way repeated measures ANOVA followed by the post-hoc student-Newman-Keuls test, compared with the nonspecific oligonucleotide control and BAA groups, respectively.

Figure 4. Differential effects of multiple-daily intrathecal injection of siRNA/p38 α and siRNA/p38 β MAPK on baseline pain thresholds (A), bulleyaconitine A (BAA)-induced mechanical antiallodynia (B), and expression of spinal p38 α (C and D) and p38 β (E and F) mRNA and protein in neuropathic rats. Neuropathic rats, induced by tight ligation of L5/L6 spinal nerves, and then received multiple-daily intrathecal injection of the vehicle (DOTAP, 30 μg/day), nonspecific oligos (5 μg/day), siRNA/p38 α (5 μg/day) or siRNA/p38 β (5 μg/day) for 7 days. The paw withdrawal thresholds were measured once a day using electronic von frey filaments. On the eighth day, a single bolus of saline (10 μL) or BAA (300 ng) was intrathecally injected and mechanical nociceptive behaviors were quantified 1 hour after injection. Spinal lumbar enlargements were immediately obtained after completion of behavioral assessments. Expressions of the mRNA of p38 α , p38 β and prodynorphin and protein of p38 α and p38 β referred to *gapdh* were determined using qRT-PCR and Western blot, respectively. The representative blots are shown in the upper panels of each panel. Data are expressed as means $\pm$ SEM (n = 6 in each group). ^{a,b}P < 0.05 using one-way or two-way repeated measures ANOVA followed by the post-hoc student-Newman-Keuls test, compared with the control and BAA groups, respectively.

To assess whether BAA-induced prodynorphin expression and mechanical antiallodynia were through the cAMP/PKA signaling, the specific adenylate cyclase inhibitor DDA and PKA activation inhibitor H-89 were employed in cultured primary microglia and neuropathic rats. Treatment with 1 μM BAA for 2 hours significantly

Figure 5. Stimulatory effects of bulleyaconitine A (BAA) on the intracellular cAMP level (A) and PKA phosphorylation (B), and blockade effects of the specific adenylate cyclase inhibitor DDA and PKA inhibitor H-89 on BAA-stimulated prodynorphin gene expression (C) in primary cultures of microglia, and spinal mechanical antiallodynia in neuropathic rats (D). Primary microglial cells were collected from the spinal cord of 1-day-old neonatal rats. For the cAMP measurement, these microglia were incubated with 1 μ M BAA for 30 minutes and the intracellular cAMP accumulation was assayed using a commercial ELISA kit. For phosphorylation of PKA and p38, 1 μ M BAA was incubated with cultured microglia for 1 hour, and subjected to Western blot analysis. The representative blots are shown in the upper panels of each panel. For gene expression, the MAPK activation inhibitors were incubated 30 minutes before BAA treatment, and primary microglial cells were collected 2 hours later. The level of dynorphin A precursor prodynorphin mRNA was determined using qRT-PCR and normalized to *GAPDH* mRNA. For mechanical antiallodynia, neuropathic rats were induced by tight ligation of L5/L6 spinal nerves, and mechanical thresholds were measured in both contralateral and ipsilateral paws. Blockade effects of DDA (E) and H-89 (F) on BAA-induced p38 phosphorylation were also assessed. Data are presented as means $\pm$ SEM ($n = 3$ in each treatment with two independent repeats in cultured primary microglial cells, and $n = 6$ in each group of neuropathic rats). ^{a,b} $P < 0.05$ using the unpaired and two-tailed Student's *t*-test or two-way repeated measures ANOVA followed by the post-hoc student-Newman-Keuls test, compared with the control and BAA groups, respectively.

increased expression of prodynorphin mRNA by 2.1 fold, whereas DDA (100 μ M) and H-89 (10 μ M)^{35,36} did not significantly affect the basal prodynorphin expression. Pretreatment (1 hour before) with DDA or H-89 completely prevented BAA-increased prodynorphin expression ($P < 0.05$ by two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 5C).

Pretreatment of neuropathic rats with DDA (1 μ g) and H-89 (10 μ g)³⁷ did not significantly affect baseline paw withdrawal thresholds in response to mechanical stimulation in both contralateral or ipsilateral paws, but completely prevented BAA-induced mechanical allodynia ($P < 0.05$ using two-way ANOVA followed by a post-hoc Student-Newman-Keuls test; Fig. 5D).

To further determine whether BAA-induced p38 phosphorylation was cAMP/PKA-dependent, DDA and H-89 were applied in cultured primary microglia. We found that pretreatment (1 hour before) with DDA (100 μ M) and H-89 (10 μ M) did not significantly affect the basal p38 phosphorylation level, but completely blocked BAA-upregulated p38 phosphorylation ($P < 0.05$ using two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 5E,F).

A GsPCR possibly mediates BAA-induced prodynorphin expression in primary microglia. To explore Gs-protein involvement in BAA-mediated cAMP production and subsequent prodynorphin expression, we employed a Gs inhibitor NF449 in cultured microglia. NF449 was identified as a selective inhibitor of the Gs signaling, with limited effects on the prototypical Gi/Go and Gq signaling³⁸. BAA treatment (1 μ M) for 30 minutes significantly increased intracellular cAMP level, whereas NF449 treatment (10 μ M)³⁹ in cultured primary microglial cells did not significantly affect the basal intracellular cAMP level. However, 30 minutes NF449 pretreatment completely inhibited BAA-increased cAMP accumulation ($P < 0.05$ using two-way ANOVA followed by a post-hoc Student-Newman-Keuls test; Fig. 6A).

NF449 treatment (10 μ M) did not significantly affect basal prodynorphin gene expression but BAA (1 μ M) markedly increased prodynorphin expression. 30 minutes NF449 pretreatment completely suppressed BAA-stimulated prodynorphin mRNA level ($P < 0.05$ using two-way ANOVA followed by a post-hoc Student-Newman-Keuls test; Fig. 6B).

Furthermore, intrathecal BAA injection (300 ng) produced a marked mechanical allodynia in the ipsilateral paws in a time-dependent manner. 30 minutes pretreatment with intrathecal NF449 (10 μ g)^{40,41} did not significantly change baseline paw withdrawal thresholds in either contralateral or ipsilateral paws, but completely prevented spinal BAA mechanical allodynia in the ipsilateral paws ($P < 0.05$ using two-way ANOVA followed by the post-hoc Student-Newman-Keuls test; Fig. 6C).

Lastly, as BAA-induced mechanical allodynia in neuropathy is clearly an *in vivo* indicator of spinal microglial prodynorphin expression and dynorphin A release^{9–11,42}, 8 specific GPCR antagonists were intrathecally employed in neuropathic rats to identify the proposed GsPCR responsible for BAA-induced dynorphin A expression. Each two groups of neuropathic rats ($n = 3$ in each group) received intrathecal injections of saline (10 μ L) or different GPCR antagonists followed by an intrathecal BAA injection (300 ng) 30 minutes later. These antagonists specifically targeted the following GPCRs, i.e., the noradrenergic β -adrenoceptor (propranolol, 1 μ g)⁴³, β_1 -adrenoceptor (landiolol, 30 μ g)⁴⁴, α -adrenoceptor (phentolamine, 10 μ g)^{45,46}, corticotrophin-releasing factor receptor (α -helical CRF(9–41), 20 μ g)⁴⁷, adenosine A1 receptor (DPCPX, 10 μ g)⁴⁸, formyl peptide receptor (cyclosporine, 1 μ g)⁴⁹, D1/D2 dopamine receptor (levo-tetrahydropalmatine, 30 μ g)⁵⁰, and glucagon-like peptide-1 (GLP-1) receptor (exendin(9–39), 15 μ g)⁵¹. Mechanical withdrawal thresholds in both contralateral and ipsilateral paws were measured before and 0.5, 1, 2 and 4 hours after the second injection. As shown in Fig. 7, intrathecal BAA injection produced a time-dependent mechanical allodynia. However, treatment with propranolol (Fig. 7A), landiolol (Fig. 7B), phentolamine (Fig. 7C), α -helical CRF(9–41) (Fig. 7D), DPCPX (Fig. 7E), cyclosporine (Fig. 7F), levo-tetrahydropalmatine (Fig. 7G), or exendin(9–39) (Fig. 7H) failed to significantly reduce BAA-induced mechanical allodynia, although they are known to sufficiently block their respective spinal GPCR activities.

Discussion

In the current study, we have dissected and proposed signal transduction pathways for aconitines (represented by BAA) to stimulate prodynorphin expression in microglia. By binding to an unclarified GsPCR - “aconitine receptor” which is possibly specifically localized on microglial cell membrane, BAA, other aconitines (such as aconitine, bullatine A and lappaconitine) and the *Aconitum* extracts are able to activate Gs-protein and in turn trigger adenylate cyclase and produce a large amount of cAMP, which further stimulates PKA and subsequent p38 β phosphorylation. The p-p38 β then translocates to the nucleus and activates the transcription factor CREB, leading to an increase in prodynorphin transcription. The proposed signal transduction pathway is presented in Fig. 8. The illustration of the entire signal transduction pathway of aconitines further supports the notion that their antinociception is through spinal microglial prodynorphin expression and dynorphin A release, but not through the interactions with voltage-gated sodium channels which is not involved in the Gs-PKA-p38-CREB pathway. Furthermore, our results also highlight the selective role of p38 β in pain transduction and provide an opportunity to identify the unclarified GsPCR, i.e., “aconitine receptor”.

CREB, a member of the basic leucine zipper family of the transcription factors, regulates a large and diverse group of gene transcription and function in cellular responses to various physiological stimuli, including neurotransmitters, growth factors, and cell stress²⁰. Specifically, the transcriptional activity induced by phospho-CREB initiates binding to CRE present in the target gene promoter⁵². Previous studies showed that CREB regulated the transcription of prodynorphin gene in neurons^{22,23}, while our current study demonstrated that BAA induced a robust CREB phosphorylation and prodynorphin expression in primarily cultured microglia, which was completely inhibited by the selective CREB inhibitor KG-501, indicating that BAA-stimulated microglial prodynorphin expression was mediated by CREB activation. In contrast, BAA did not induce phosphorylation of NF- κ B,

Figure 6. Blockade effects of the Gs-protein inhibitor NF449 on bulleyaconitine (BAA)-stimulated cAMP accumulation (A) and prodynorphin mRNA expression (B) in primary cultures of microglia, and spinal mechanical antiallodynia in neuropathic rats (C). Primary microglial cells were collected from the spinal cord of 1-day-old neonatal rats. For the cAMP measurement, microglial cells were incubated with 1 μ M BAA for 30 minutes and subjected to ELISA analysis of the intracellular cAMP level using a commercial ELISA kit. For gene expression, the cultured cells were collected 2 hours after incubation with test reagents and subjected to qRT-PCR analysis of the dynorphin A precursor prodynorphin mRNA referred to GAPDH mRNA. For mechanical antiallodynia, neuropathic rats were induced by tight ligation of L5/L6 spinal nerves, and mechanical thresholds were measured in both contralateral and ipsilateral paws. Data are presented as means $\pm$ SEM ($n = 3$ in each treatment with two independent repeats in cultured primary microglial cells, $n = 6$ in each group of neuropathic rats). ^{a,b} $P < 0.05$ using two-way repeated measures ANOVA followed by the post-hoc student-Newman-Keuls test, compared with the control and BAA groups, respectively.

which is also a pleiotropic factor to promote transcription of a wide variety of genes. In microglia, activated NF- κ B translocates into the nucleus and regulates the synthesis and release of proinflammatory cytokines to play a pivotal role in neuroinflammation⁵³. However, bullatine A and lappaconitine did not significantly inhibit microglial expression of proinflammatory cytokines, including tumor necrosis factor (TNF)- α , interleukin (IL)-6, and IL-1 β ^{11,12}. Both results rule out the possible involvement of NF- κ B in mediation of BAA signaling transduction in microglia.

CREB is initially identified as a PKA substrate and phosphorylation of the serine-133 site makes it function as a stimulus-dependent transcriptional activator²¹. Another alternative pathway of the p38/CREB is also observed later, i.e., CREB phosphorylation can also be directly induced by p38 MAPK at the same serine 133 site²². Thus, these classic and alternative pathways do exist in different cells and respond to different gene signaling^{54,55}. In our study, we found that selective p38 activation inhibitor SB203580 was able to entirely abolish BAA-activated microglial CREB phosphorylation and prodynorphin expression, suggesting that p38 MAPK activation plays an obligatory intermediate role in PKA-induced CREB's regulation of prodynorphin expression in microglia.

We demonstrated that BAA specifically activated p38 without a significant effect on ERK or JNK activation. The selective p38 inhibitor but not the ERK or JNK inhibitor could entirely eliminate BAA-increased prodynorphin expression in cultured primary microglia. Our current data were supported by recent studies showing that aconitine treatment of myocardial cells induced p38 phosphorylation and cell apoptosis, both of which were significantly attenuated by SB203580 treatment⁵⁶, and that the microglial inhibitor minocycline completely inhibited aconitine-, BAA- and bullatine A-increased dynorphin A gene and protein expression and antinociception in neuropathy^{9–11,42}. Minocycline has been shown to inhibit spinal p38 activation^{57,58}, particularly in a neuropathic pain condition⁵⁹, although it was also shown to inhibit ERK⁶⁰ and JNK activity⁶¹. Taken altogether, our data

Figure 7. Ineffectiveness of the specific antagonists of the noradrenergic β -adrenoceptor, β_1 -adrenoceptor, α -adrenoceptor, corticotrophin-releasing factor receptor, adenosine A1 receptor, formyl peptide receptor, D1/D2 dopamine receptor and glucagon-like peptide-1 (GLP-1) receptor on bulleyaconitine (BAA)-induced spinal mechanical allodynia in neuropathic rats. Neuropathic rats, induced by tight ligation of L5/L6 spinal nerves, received intrathecal injection of saline or propranolol, landiolol, phentolamine, α -helical CRF(9–41), DPCPX, cyclosporine, levo-tetrahydropalmatine or exendin(9–39) followed by an intrathecal injection of BAA 30 minutes later. Mechanical withdrawal thresholds in both contralateral and ipsilateral paws were measured before and 0.5, 1, 2 and 4 hours after the second injection. Data are presented as means $\pm$ SEM ($n = 3$ in each group).

Figure 8. Illustration of the proposed signal transduction pathway of bulleyaconitine A (BAA), bullatine A, lappaconitine, and the *Aconitum* extracts-induced prodynorphin expression in microglia. Following activation of the “aconitine receptor”, the Gs-protein, cAMP/PKA, p38 β (but not ERK, JNK or p38 α) MAPK and CREB (but not NF- κ B) signals are successively activated, which mediates prodynorphin expression.

revealed that BAA specifically activated p38 and subsequent CREB phosphorylation leading to prodynorphin expression. Furthermore, our recent study showed that GLP-1 receptor agonism-induced β -endorphin expression was solely mediated by a p38-dependent CREB activation⁶². These data are of significance in pain transmission and transduction, as activation of p38 is an important intracellular signaling event which exclusively occurred in microglia and in turn regulated pain hypersensitivity, whereas activation of ERK and JNK activation usually occurs in dorsal horn neurons or astrocytes (but not in microglia) after spinal nerve injury⁶³. Furthermore, p38 is a downstream target of several signal molecules²⁷ and activation of cAMP/PKA to phosphorylation of MAPKs has been shown to be an important signal transduction process. We demonstrated that BAA-induced phosphorylation of p38 and prodynorphin expression were completely suppressed by DDA and H-89, highlighting that BAA-induced p38 phosphorylation is cAMP/PKA-dependent in microglia.

However, our finding seems contradictory as it is known that p38 phosphorylation was also involved in expression of pro-inflammatory cytokines, IL-1 β , IL-6, and TNF- α ^{64,65}. It is true that p38 has α , β , γ , and δ isoforms and that α and β are the major isoforms in the mature nervous system^{26,34,66}. The p38 α isoform was responsible for expression of pro-inflammatory cytokines^{67–70}. While p38 β appeared to be the most abundant isoform in spinal microglia³⁴, it was not involved in inflammation and tissue damage^{69,70}. We recently evidenced that GLP-1 receptor agonism-induced β -endorphin expression and mechanical allodynia in neuropathy were fully mediated by p38 β activation, whereas lipopolysaccharides-induced expression of proinflammatory cytokines was partially mediated by p38 α activation⁶². Our data further confirmed that p38 β activation mediates BAA-induced prodynorphin expression in cultured primary microglial cells.

Many investigators have demonstrated that nerve injury would induce p38 phosphorylation in spinal cord microglia, which contributed to development and maintenance of neuropathic pain²⁶. For instance, p38 activation in the neuropathic pain state exclusively occurred in microglia, but not in neurons or astrocytes in the dorsal horn⁷¹. However, there are contradictory findings regarding p38 as a target molecule for treatment of chronic pain in experimental animals, especially in established neuropathic pain. It was reported that selective p38 activation inhibitor SB203580 cannot reverse neuropathic pain when given to animals after neuropathy was established⁷². Our recent study reported that knockdown of spinal p38 α or p38 β expression was not antiallodynic⁶². Our current results demonstrated that multiple-daily injections of siRNA/p38 α or siRNA/p38 β did not alter mechanical thresholds in the ipsilateral paws in neuropathic rats. All these results together suggest that spinal p38 or its α or β isoform does not regulate basal pain states.

Our study revealed that BAA treatment dose-dependently enhanced cAMP accumulation and PKA phosphorylation in cultured primary microglial cells. BAA-induced prodynorphin expression in microglia were completely blocked by DDA and H-89, and particularly the specific Gs-protein inhibitor NF449, suggesting that BAA-increased prodynorphin expression was mediated by the Gs/cAMP/PKA signaling pathway. Thus, we speculate that a GsPCR expressed on microglial cell membrane could be the target molecule for BAA to stimulate prodynorphin expression and dynorphin A release. We tentatively name the unidentified GsPCR as the “aconitine receptor”.

GPCRs are the largest family of receptors to respond for a variety of stimuli, ranging from neurotransmitters and hormones to light and mechanical pressure, and represent targets for approximately 40% of all approved drugs in the clinic. It would be extremely valuable to illustrate the chemical identity of the “aconitine receptor” on microglia. In an effort to identify the “aconitine receptor”, we assessed the blockade ability of several specific GPCR antagonists in neuropathy on BAA mechanical antiallodynia, which has been demonstrated to be induced by spinal microglial dynorphin A expression (Li *et al.*, 2016a; Li *et al.*, 2016b; Huang *et al.*¹¹; Huang *et al.*⁴²). The GPCR receptors assessed in our study included the β -adrenoceptor (and β_1 -adrenoceptor), α -adrenoceptor, corticotrophin-releasing factor receptor, adenosine A1 receptor, formyl peptide receptor, D1/D2 dopamine receptor, and GLP-1 receptor. However, all the antagonists failed to alter BAA mechanical antiallodynia in neuropathy. It is worth noting that the D1/D2 dopamine receptor antagonist levo-tetrahydropalmatine did not alter BAA-induced mechanical antiallodynia, suggesting that BAA-induced dynorphin A expression is not involved in activation of D1/D2 dopamine receptors in microglia, whereas activation of D1 dopamine receptor was reported to stimulate dynorphin A expression in a cAMP/PKA/CREB signaling-dependent manner in nucleus accumbens and striatonigral neurons (Carlezon *et al.*²³; Muschamp and Carlezon, 2015). Further studies are warranted to utilize techniques, such as GsPCR binding or functional screening assays of large scale and chemical proteomics, to identify the particular GsPCR involved in BAA-induced spinal microglial dynorphin A expression and mechanical antiallodynia in animals.

Materials and Methods

Drugs and reagents. BAA was purchased from Zelang Bio-Pharmaceuticals (Nanjing, China) and NF449 was from Tocris Bioscience (Bristol, UK). 2',5'-dideoxyadenosine (DDA) and N-(2-(p-bromocinnamylamino)ethyl)-5-isoquinolinesulfonamide (H-89) were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA), while KG-501 and SP600125 were from Sigma-Aldrich (St. Louis, MO, USA) and SB203580 and U0126 were from Selleck Chemicals (Houston, TX, USA). Levo-tetrahydropalmatine was a gift from Dr. Yan Zhang at Shanghai Jiao University School of Pharmacy. KG-501, SB203580, U0126, and SP600125 were dissolved in dimethyl sulfoxide (DMSO) and made 20% stock solution in saline, while other drugs and reagents were dissolved in 0.9% normal saline.

siRNA and transfection. The small interference of double-stranded RNA (siRNA) targeting the cDNA sequence of the rat p38 α (siRNA/p38 α), p38 β (siRNA/p38 β), and the nonspecific oligonucleotides were designed and synthesized by Shanghai GenePharma (Shanghai, China). Their sequences were siRNA/p38 α , 5'-GCACGAGAAUGUGAUUGGUTT-3' and 5'-ACCAAUCACAUUCUCGUGCTT-3'; siRNA/p38 β , 5'-GCACGAGAACGUCAUAGGATT-3' and 5'-UCCUAGACGUUCUCGUGCTT-3'; nonspecific oligonucleotides, 5'-UUCUCCGAACGUGUCACGUTT-3' and 5'-ACGUGACACGUUCGGAGAATT-3'. To formulate siRNAs, 1,2-dioleoyloxy-3-trimethylammonium-propane (DOTAP, Sigma-Aldrich) was dissolved in water (5 mg/mL, pH 7.0). For the *in vitro* transfection, 50 μ L diluted siRNA solution was added into 50 μ L diluted DOTAP solution in a DOTAP:RNA mass ratio of 1:8, thoroughly mixed, and then incubated at the room temperature for 15 minutes.

Primary microglia were seeded into 6 or 24-well plates and grown overnight. The siRNA-DOTAP complex was then added into the plates with 300 μ L/500 μ L basic Dulbecco's modified Eagle's medium (DMEM) to make the final siRNA concentration of 5 μ g/mL. The plates were then incubated in a humidified incubator with 5% CO₂ at 37 °C for 5 hours. Cells were further cultured for 24 hours after refreshing with the cultural medium. For the *in vivo* experiments, the siRNA-DOTAP complex was formulated in the same DOTAP:RNA mass ratio of 1:8 and intrathecally injected into rats for successive 7 days.

Experimental animals. Male adult (200 $\pm$ 20 g body weight) and 1-day-old Wistar neonatal rats were purchased from the Shanghai Experimental Animal Institute for Biological Sciences (Shanghai, China). The adult rats were maintained four per cage, received food and water *ad libitum*, and housed in the Shanghai Jiao Tong University Experimental Animal Center (Shanghai, China) with thick sawdust bedding at standard room temperature (22 $\pm$ 2 °C), under conditions of a 12/12-hr reversed light-dark cycle (7:00 am–7:00 pm). The adult rats were accustomed to the laboratory environment for 3–5 days before our experiments. Experimental groups (n = 6 in each group except for the target screening study as indicated in the text) were randomly assigned, and the investigator was blinded for the behavior tests. This study was approved by the Animal Care and Welfare Committee of Shanghai Jiao Tong University and carried out in accordance with the animal care guidelines of the US National Institutes of Health.

Primary culture of microglial cells. Microglial cells were isolated from the spinal dorsal horn of 1-day-old neonatal rats. The isolated spinal cords were minced and then incubated with 0.05% trypsin solution. Dissociated cells were suspended in DMEM supplemented with 10% (vol/vol) fetal calf serum and penicillin (100 U/mL) and streptomycin (100 μ g/mL) and plated in 75-cm² tissue culture flasks (1 $\times$ 10⁷ cells/flask) that were pre-coated with poly-L-lysine and maintained in a 5% carbon dioxide incubator at 37 °C. After culture for 8 days, microglial cells were prepared as floating cell suspensions by shaking the flasks at 260 rpm for 2 hours. The aliquots were transferred to plates and unattached cells were removed by washing with serum-free DMEM. Harvested microglial cells showed a purity >95%, as determined by the OX42 immunoreactivity (Gong *et al.*, 2014).

RNA isolation and quantitative reverse transcription-polymerase chain reaction (qRT-PCR). The spinal dorsal lumbar enlargements were collected and homogenized using an electronic microhomogenizer at 4,000 rpm for 10 seconds in TRIzol (Invitrogen, Carlsbad, CA, USA) on ice, while total RNA from cultured microglial cells was also isolated directly using TRIzol. The RNA samples of 1 μ g each were reversely transcribed into cDNA using a ReverTra Ace qPCR RT-Kit (Toyobo Co., Osaka, Japan). qPCR was then

carried out in a Mastercycler ep realplex (Eppendorf, Germany) using Realmaster Mix (SYBR Green I) (Toyobo Co.) according to a previous study⁷³. The fold change was calculated using the $2^{-\Delta\Delta C_t}$ method after normalization to *GAPDH*. The primers were *GAPDH* (5'-CCA AGG TCA TCC ATG ACA AC-3' and 5'-TCC ACA GTC TTC TGA GTG GC-3')⁵¹ and *PDYN* (5'-ACT GCC TGT CCT TGT GTT CC-3' and 5'-CCA AAG CAA CCT CAT TCT CC-3')⁷⁴.

Protein extraction and Western blot. Cultured microglia were seeded into 6-well plates at a density of 5×10^6 cells per well and grown overnight and then harvested and lysed in the radioimmunoprecipitation assay (RIPA) lysis buffer with addition of the phosphates inhibitor cocktail and the protease inhibitor cocktail (Biotool, Houston, USA). Briefly, cells were scraped into the lysis buffer and homogenized by passing through a 21G needle and cell lysates were centrifuged at 13,000 g at 4 °C for 15 minutes. The supernatants were then collected and the protein concentration was quantified using a bicinchoninic acid (BCA) assay according to the manufacturer's protocol (Beyotime Institute of Biotechnology, Jiangsu, China). The homogenates were diluted 1:1 (v/v) with 5× sodium dodecyl sulfate (SDS) sample buffer (Bio-Rad, Hercules, CA, USA) and boiled for 10 minutes at 95 °C in the SDS sample buffer. The protein samples were then separated in 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) gels and transferred onto a polyvinylidene fluoride (PVDF) membrane using the electrophoretic method. The membrane was then blocked in 5% skim milk powder in Tris-based saline-Tween 20 (TBST) at room temperature for one hour, and then incubated at 4 °C overnight with rabbit monoclonal primary antibodies raised against phospho-p38, phospho-ERK, phospho-JNK, p38 α , p38 β , phospho-CREB (Cell Signaling Technology, Danvers, MA, USA) at a dilution of 1:1,000, anti-phospho-PKA catalytic subunit (Santa Cruz Biotechnology) at a dilution of 1:200, and a mouse monoclonal antibody against GAPDH (Protein Tech Group, Chicago, USA) at a dilution of 1:4,000, respectively. The membranes were then washed four times in TBST (10 minutes each) and further incubated 1 hour with a secondary peroxidase conjugated goat anti-rabbit and goat anti-mouse antibody, and washed four times with TBST. Protein bands were visualized using the IRDye 800-conjugated affinity purified goat anti-rabbit IgG and IRDye 700-conjugated affinity purified goat anti-mouse IgG (Cell Signaling Technology, Danvers, MA, USA) in the Odyssey Infrared Imaging system (Li-Cor Biosciences, Lincoln, NE, USA). The band intensity was quantitated using a computer-assisted image analysis program (ImageJ Software, National Institutes of Health, Bethesda, MD, USA) and compared to the house-keeping protein, i.e., the band intensity ratios of phospho-p38/GAPDH, phospho-ERK/GAPDH, phospho-JNK/GAPDH, phospho-PKA/GAPDH, p38 α /GAPDH, p38 β /GAPDH, and phospho-CREB/GAPDH were obtained to quantify the respective target protein expression^{51,75}.

Intracellular cAMP assay. Cultured microglial cells (5×10^6) were seeded into 6-well plates and treated with the phosphodiesterase inhibitor IBMX (Sigma-Aldrich) at 0.5 mM in serum-free medium for 30 minutes before treatment with different concentrations (10^{-10} , 10^{-9} , 10^{-8} , 10^{-7} , 10^{-6} , and 10^{-5} M) of bulleyaconitine A. 30 minutes after incubation, microglial cells were lysed using the R&D Cell Lysis Buffer and cAMP release was determined using a commercial cAMP enzyme immunoassay kit (R&D Systems, Minneapolis, USA) according to the manufacturer's protocols. The concentration of cAMP was calculated using a standard curve using the Assay Zap (Biosoft, Cambridge, UK) and normalized. Data represented two independent experiments with triplicate⁷⁶.

Intrathecal catheterization and injection in rats. A 18-cm polyethylene catheter (PE-10: 0.28 mm inner diameter and 0.61 mm outer diameter) (Clay Adams, Parsippany, NJ, USA) with a volume of 13 μ L was inserted into the rat lumbar level of the spinal cord under inhaled isoflurane anesthesia (4% for induction and 1% for maintenance) run by an anesthetometer (Ugo Basile Gas Anesthesia System, Comerio, Italy). Two days after recovery from anesthesia, the installation of the catheter in the spinal cord was verified by administering 4% lidocaine (10 μ L followed by 15 μ L of saline for flushing). Rats that did not induce motor impairment following insertion of the intrathecal catheter and developed immediate bilateral paralysis of the hindlimbs following intrathecal lidocaine were selected for the study. For the intrathecal delivery, 10 μ L of the drug solution was administered in a 50- μ L microinjector (Shanghai Anting Micro-Injector Factory, Shanghai, China) followed by 15 μ L saline flush⁷⁷.

Rat neuropathic pain model and behavioral assessment of mechanical allodynia. The unilateral ligation of two spinal nerves was performed under inhaled isoflurane anesthesia run by the anesthetometer. The left L5 and L6 spinal nerves were isolated and tightly ligated with 6-0 silk thread. After ligation, the wound was sutured and the rats were allowed to recover. As intrathecal injection was needed in this study, the intrathecal catheterization was performed in rats at the same time just before spinal nerve ligation. Of the spinal nerve-ligated animals, only those with marked unilateral allodynia to mechanical stimulation (hindlimb withdrawal thresholds in the operated side <8 g) and no major impairment were included in the study. Drug testing started 2–4 weeks after spinal nerve ligation surgery^{78,79}.

To evaluate mechanical allodynia, the animals were acclimatized for at least 30 minutes to the test environment, namely a plexiglass box on a metal grid (0.5 × 0.5 cm). The hindpaw withdrawal threshold was measured by using a 2450 CE Electronic Von Frey hair (IITC Life Science Inc, Woodland Hill, CA, USA). The electronic hand-held transducer with a No. 15 monofilament (with forces ranging from 0.1 to 90 g) was applied perpendicularly to the medial surface of the hindpaws with the increasing force until the rat suddenly withdrew or licked the hindpaw. The lowest force to produced a withdrawal response was considered to be the threshold. Three repeated measurements were made at intervals of approximately 5 minutes and were averaged for each hindpaw at each time-point^{78,79}.

Statistical analysis. For the concentration–response curve analysis, the parameters, i.e., the minimum, maximum (E_{max}), median effective concentration (EC_{50}) and Hill coefficient (n) were calculated from individual concentration–response curves. To determine the parameters of the concentration–response curves,

values of response (Y) were fitted by non-linear least-squares curves to the relation $Y = a + bx$, where $x = (C)^n / (EC_{50}^n + (C)^n)$, to give the value of EC_{50} and b (E_{max}) yielding a minimum residual sum of squares of deviations from the theoretical curve⁸⁰.

Data were presented as means $\pm$ standard error of the mean (SEM), and there were no missing data in this study. Statistical significance was evaluated using unpaired and two-tailed Student's *t*-test or a one-way or two-way repeated measured analysis of variance (ANOVA) with the 5.01 Prism program (GraphPad Software Inc., San Diego, CA, USA). This was followed by a post-hoc Student-Newman-Keuls test when a statistically significant drug (dose) effect was observed (for the one-way ANOVA, the factor was drug (dose); for the two-way ANOVA, the factors were drug (dose), time, and their interaction). Probability values were two-tailed, and the statistical significant criterion *P* value was set to be 0.05.

Acknowledgements

This study was supported in part by grants from the National Natural Science Foundation of China (#81673403) and Shanghai Industrial Translational Projects (#15401901300). We thank Dr. Yan Zhang at Shanghai Jiao Tong University School of Pharmacy for her kind gift of levo-tetrahydropalmatine.

Author Contributions

Conceived and designed the experiments: Y.X.W., T.F.L.; performed the experiments: T.F.L., H.Y.W., Y.R.W., X.-Y.L.; analyzed the data: T.F.L., Y.X.W.; and wrote the paper: Y.X.W., T.F.L.
